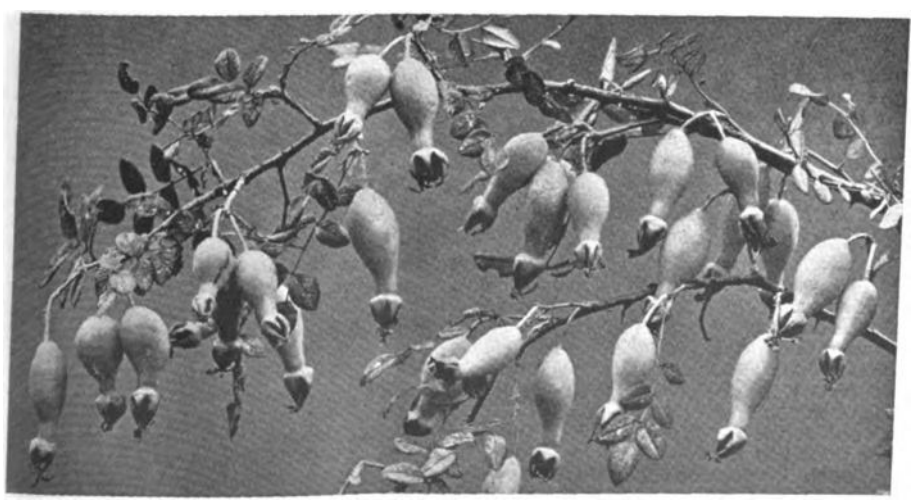
I had been informed that I might expect this autumn crop of bloom, but had not anticipated so delightful a mass of charming colour. The plant is by no means large, and where a shrub of small dimensions, neat but extremely graceful of habit and unusual liberality in production of flowers is desired—and we have not too many autumn-flowering shrubs—here is a real gem which, given a fibrous soil, will make itself comfortable and happy. This plant was, I believe, raised as a seedling in the Daisy Hill Nurseries, Newry, Ireland, by the owner, Mr. T. Smith.



R. MOYESII IS AN EXCELLENT DUAL PURPOSE ROSE.
It is as brilliant in autumn as it is in summer when draped with its long flask-shaped fruits.

A Dahlia that is Dainty and Charming.

THE subject which forms this note bears the pleasing name of "Our Annie," and it belongs to the section known as the "charm" dahlias, which are peony-flowered on a small, refined scale, and are more suitable than their heavier relatives for cut flower decorations. In the garden they contrive, by industrious production of bloom, to paint as effective a picture as the massive giants.

Personal taste must always affect choice of varieties in such flowers as dahlias; but it is noteworthy that "Our Annie," growing beside a representative collection of the best of modern varieties, never fails to draw some word of praise from visitors who count dahlias among their favourite flowers. It is shapely, grows on a sturdy, compact plant less than 3ft. high, its blossoms nicely poised on lengthy, wiry stems, and its colour is a fresh and pleasant shade of pink which may legitimately be termed shrimp pink.

THE BUSY MAN'S PAGE

Darwin and May-Flowering Tulips.

FOR general usefulness these are invaluable owing to their accommodating nature for grouping, massing and as cut-flower specimens. The flexible stems are particularly amenable to arrangement in vases.

While it is better to have lifted and dried the bulbs following the decay of the foliage, yet, if through pressure of work or other circumstance this has been omitted, it is still permissible to do the job now with every prospect of success. Later the bulbs become active and disturbance is harmful.

Replant in good garden soil and in a fresh situation, about 4ins. deep in this case, varying the depth according to the texture of the soil. It is not profitable that they occupy the same soil for more than a couple of years at most. The results of such practice is small bulbs and, moreover, decrease in length of stem and size of flower, with a tendency to encourage "fire" in flower, "sclerotia" in bulbs.

Twelve Good Darwin Tulips for Present Planting.

ANDROMAQUE.—*Brilliant garnet red flowers with a white base. A tall and vigorous grower.*

BARONNE DE LA TONNAYE.—*A deep rose variety with a pale margin. Late flowering.*

CLARA BUTT.—*One of the most popular of all the Darwins. Colour delicate rose.*

ERGUSTE.—*Deep heliotrope shaded with silver. The flowers are somewhat pointed.*

FARNCOMBE SANDERS.—*One of the best bedding Darwin tulips. An immense flower of vivid cherry red.*

ISIS.—*A blood-red variety with tall, strong stems.*

KING HAROLD.—*Large handsome flowers of glossy crimson maroon.*

MARCONI.—*Deep purple with white base. A well formed flower and the finest purple Darwin.*

PETRUS HONDIUS.—*Bright carmine rose. Quite a distinct colour.*

PRIDE OF HAARLEM.—*Large finely formed flowers of vivid rose and white at the base. A beautiful bedding variety.*

THE BISHOP.—*Rich purple blue-shot flowers. Attractive in association with soft pale pink tulips.*

YELLOW DARWIN.—*Large canary yellow blooms. Not a true Darwin, but similar in shape.*

Anchusa Italica, Dropmore Variety.

THE stock of this first-rate border plant can be easily increased at this time by means of vegetative propagation, consisting in digging up the root-stalk carefully and dividing the thong-like roots in small pieces (about 3ins.). Dibble these into boxes filled with light sandy soil, place in a cool house or frame, when plants suitable for spring planting will result.

Divide and Replant your Phloxes.

THIS is a particularly suitable period, on passing out of flower, for the planting or lifting, division and replanting of phloxes. The stems being still erect, assist greatly in determining the various heights and habits of the component varieties, thereby facilitating the placing and arrangement of these excellent border plants in groups to provide masses of colour.

Trench the ground thoroughly, choosing a new situation of a like medium, if possible, for replanting. Apply a good dressing of artificial manure, plant young, vigorous outside pieces firmly and fairly close together. Endeavour, in after cultivation, to promote the strong growth to be self-supporting, obviating, if possible, the necessity for staking.

Wintering Geraniums in Safety.

AMATEURS seem to have confused ideas about the safe wintering of geraniums. One very good plan is to lift the plants from the open before frost blackens them. Most of the soil round the roots is then shaken off, the larger leaves are cut away and the plants placed firmly in pots just large enough to hold the roots. Very, very little water suffices to keep them safe; too much water and absolute dryness are both to be avoided, more especially too much water. A second plan is to get the plants thoroughly hardened as they stand in the open; this is done by cutting away most of the leaves, all sucker shoots, and by pinching well back all the upper branches. Later, and before frost, they are lifted, potted tightly in boxes or pots of soil, as many as can be put in comfortably. Geraniums in the greenhouse must be kept dry, but not dust dry. Let the plants remain just as they are, avoid too wet a soil, give very little water and none at all unless the compost begins to dry up. Safety from frost and avoidance of excessive soil moisture are the two important points.

ANCHUSA ITALICA DROPMORE VARIETY MAKES A CHARMING BLUE BORDER WHEN GROWN IN THE MASS.
Increase your stock of it now.

Protecting Plants from Early Frosts

BRACKEN, heather or straw, if placed along the roots on the windward side, will help to prolong the life of many annuals, and autumn seedlings may be protected in the same way. Winter greens, such as broccoli and cabbage, benefit greatly if the soil is drawn up round the stalks to a height of several inches as the winter advances. If, when planting out, the ground is slightly ridged in the opposite direction to that of the prevailing winds and the greens planted in the shallow trenches, they will be considerably protected.

Marrows and outdoor tomatoes can be protected at night with old muslin, which is easily removed during the day. A very amateurish, but none the less effective, form of protection is by covering with old newspapers. The disadvantage in doing this is that they blow away easily and soon become sodden during rain.

At night sacks should be placed over the glass of frames containing seedlings, and during severe frost they should have the additional protection of dry bracken or straw. The value of bracken as a guard against frost cannot be over-estimated. Any plant or young tree that is likely to suffer owing to being in an exposed position may be protected by a barricade of bracken on the side exposed to the cold winds. Do not simply dump the bracken in a heap, or the first wind will scatter it. Build it up and keep it in position with wire hoops, sticks or string stretched over it and pegged down.

Plant Kerria Japonica for Wall Decoration.

AMONG flowering shrubs that brings welcome colour in a garden in late spring and early summer, Kerria japonica, with its bright orange globular blossoms, is a favourite with many. It has the advantage of lasting a long time in beauty, and when a bush has once become established, is seldom disturbed, going for years without needing much—or, indeed, with village people, receiving scarcely any attention, except to restrain growth occasionally. Any pruning which requires to be done should be undertaken as soon as the flowering season is over. Propagation is effected by cuttings taken of half-ripened shoots. Soil seems to be a secondary consideration in regard to this old-fashioned shrub, as it may be seen growing well in quite different localities widely apart.

Mostly one finds it in bush form, but on several occasions I have met with it trained over a cottage wall by some enterprising tenant, and when thus grown it is very charming when in bloom. It associates well with Pyrus (Cydonia) japonica and its various forms. November will soon be upon us with its busy planting-time, when kerrias may safely be removed.

THE JOY OF MAKING A NEW GARDEN

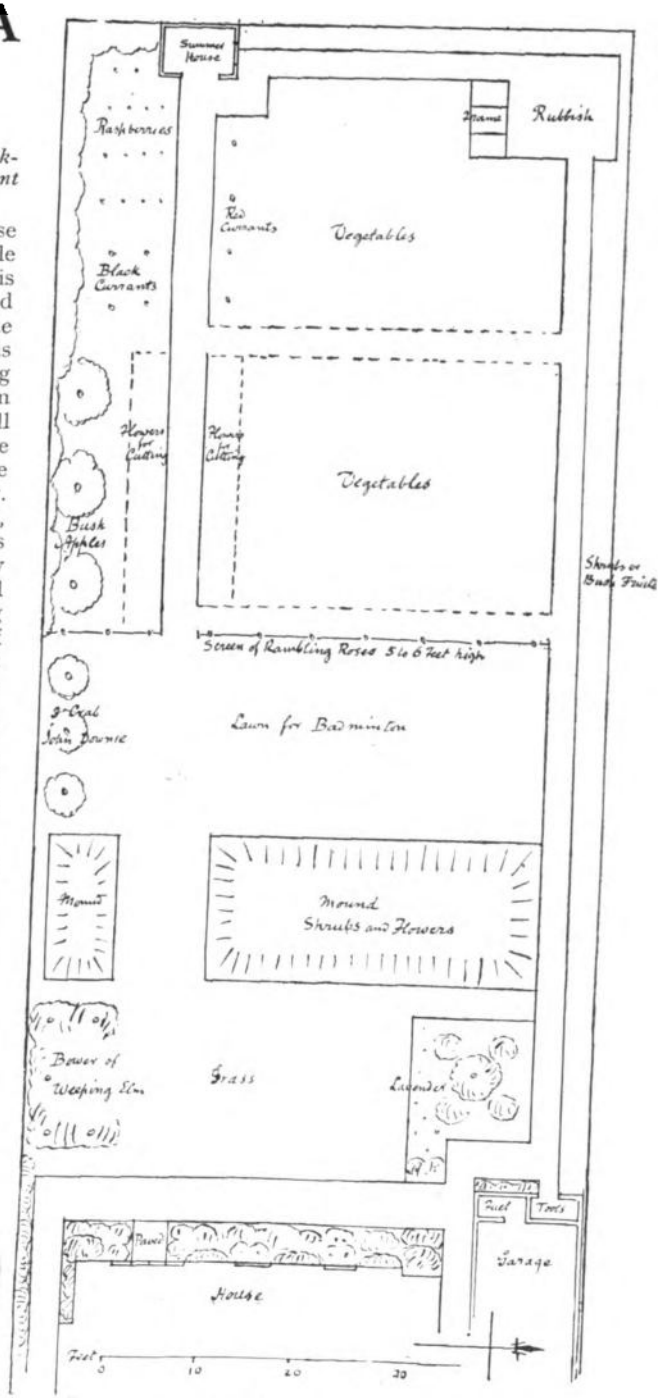
By GERTRUDE JEKYLL.

In this article suggestions are given for the planning and planting of a back-garden plot approximately 125ft. long by 50ft. wide. Plans for the front garden of this house were given in last week's issue.

WHEN planning the arrangement of a piece of ground whose length is several times greater than its width, it is advisable to treat it in separate sections across and across. This not only corrects the impression of a narrow strip, but each divided portion can be made individually interesting by being given some distinct character of its own. In the garden in question this is helped by the fact of there being a quantity of soil, that was dug out of the foundations, having been deposited a few yards from the garden front of the house. If the ground sloped down-hill away from the house, this could easily be disposed of by some levelling; but in this case the land slopes the other way, the house being near the lowest level and the vegetable ground on the higher. But this mass of soil gives the opportunity of making a mound, sloping away easily on all sides, to be planted with low shrubs and flowers. It could, alternatively, if rough stone was easily available, be made into a rock garden or be a nearly level mound retained by a few courses of dry walling for planting; but sloping it nearly equally all ways is, perhaps, the best, and lends itself to the most effective planting. The smaller mound on the left would be treated in the same way. From the front of the house to the foot of the mound should be one level, the little lawn for badminton should also be level; the mound would, therefore, be less in height on the play lawn side, and the space between the two mounds will be a slope up from one level to the other. If the rise was more considerable, it would be best to have three steps up, at any point that was found most convenient.

It is always best that the planting close against a house should have the effect of being fairly permanent and should be mostly evergreen. There should be a laurustinus at each end, and smaller shrubs, such as rosemary, lavender and the beautiful Olearia Gunni, with pink china roses to look in at the windows. As there are no shutters on this side, there will be room for three good wall plants, Escallonia macrantha, Ceanothus dentatus and a white jasmine. The shrub clump at the northern end of the small home lawn would come well, and would help the feeling of privacy near the house. It should have some choice shrub of fair size in the middle, preferably a Magnolia stellata, with four smaller shrubs—cassinia would be suitable—and a good planting of lavender on the sunny side, with two rosemary next to the path matching two of the same at the angle on the house side. A vine should be planted near the angle of the fuel place at the end of the garage, and could be trained round along the south side of the garage

THE BACK GARDEN AS IT NOW STANDS, SHOWING THE MOUND IN THE FOREGROUND WHICH CAN BE EFFECTIVELY PLANTED WITH SHRUBS AND FLOWERS.



THE PROPOSED DESIGN FOR THE PLOT.

wall, and would show handsomely at the end of the path in front of the house. As the site is open on all sides, some shade on the little home lawn is badly wanted. There can be nothing better than a bower of weeping elm. It is true that it needs some care at first, for there must be some kind of simple framework for training the branches. Those outside will hang down to form the walls, but the inner branches must be guided horizontally to make the roof. The five elms are standards with stems 7ft. 6ins. high. But if it is properly done there will be some shade the first year after planting, then every season it becomes better both for use and appearance, and soon becomes a delightful and roomy green parlour.

The small play lawn will have three Crab John Downie at the southern end

Digitized by Google

John Downie is the prettiest of the fruiting crabs, beautiful both in bloom and when loaded with its little apples. The fruits are eagerly welcomed by the careful housewife, for they make a jelly which is not only the best of its kind, but is of a lovely colour and will certainly be much admired when friends come to tea in the elm bower.

The pleasure part of the garden will be shut off from the vegetable quarters by a screen of rambling roses, with perhaps a rose arch over the two paths. The path down the kitchen garden forms one line, with the centre between the two mounds. This general axial line is demanded by the double glazed doors of the sitting-room leading out to the garden. For the depth of the first vegetable quarter a border on each side would give flowers for house decoration. The dotted lines across the vegetables are not meant for made paths, but only for easy access to the crops. If there can be a well built summer-house at the west end, it is a thing that is most desirable; in fact, if the depth of the summer-house, as shown, could be continued southward, filling up all that corner with an open shed, it would be found to be of the greatest use for housing the wheelbarrow, sticks and stakes and the many things that are wanted about a garden, and for which there would not be space in the small place for tools at the end of the garage.

THE GREAT AUTUMN SHOW

THE Holland Park Show, which opened on Tuesday, September 21st, and which remained open for two following days, was undoubtedly one of the finest autumn shows staged under the auspices of the Royal Horticultural Society. For the time of year, the wealth of colour and flower was magnificent. The exhibits of roses were almost as good, if not better than when at their height in midsummer; while the general herbaceous groups of summer-flowering perennials were a blaze of colour. In addition, real autumn flowers in dahlias, chrysanthemums and Michaelmas daisies were added to the display, and shrubs, instead of being in the forefront, lagged behind. Autumn colour in foliage and berry is lacking so early in a season such as we have experienced, but the vivid greens rather enhanced the colour of the other groups, and in that way the delicate tints of autumn, although missed, were not exactly necessary. The exhibitors who staged groups at the show and the Secretary of the Royal Horticultural Society deserve every credit for the high standard of the show, which will do much to popularise this important event in the gardener's calendar.

MESSRS. SUTTON'S CENTRAL EXHIBIT OF BRILLIANTLY COLOURED ZINNIAS.

BORDER FLOWERS.

One of the outstanding features of the show was the excellent exhibits of border plants. Over forty different firms staged groups of this class, and some of the finest of autumn-blooming perennials were exhibited. It is at this time, when the work of replanting and renovating the herbaceous border is at hand, that it is especially interesting and useful to take notes of good border plants which are seen at shows or in gardens. Every gardener should keep up to date with the work which is being carried on by plant hybridists, for many of their new introductions, such as new Michaelmas daisies, phloxes and kniphofias, are exceedingly valuable border plants and great improvements on the old varieties.

Gold-flowered perennials which bloom during August and September are numerous, and each firm exhibited some of them. Messrs. Waterers had excellent specimens of Helianthus sparsifolius, a sunflower with rich yellow blooms, and mass of Solidago Golden Wings, the finest of the golden rods. Mr. E. Ballard exhibited Solidago Ballardii, a recent introduction which should prove of great value. Messrs. J. Cheal showed, among a general collection of herbaceous flowers, Rudbeckia Newmanii, a golden yellow cone flower with an almost black centre. Helianthus The Marshal and H. Lodden Gold, both shown by the Chalk Hill Nurseries, are effective autumn border plants. Many interesting perennials were staged by Mr. Amos Perry, and in his collection was the yellow-flowered Achillea eupatorium Parker's var. Among the summer-blooming gold-flowered perennials Mr. B. Ladham showed Coreopsis auriculata superba, and C. Bedding Queen. Both of these perennials are exceedingly floriferous and valuable for the border or for cutting. Hemerocallis aurantiaca major, a beautiful day lily with apricot-coloured blooms, was shown by Mr. Maurice Prichard.

Kniphofias and montbretias made brilliant splashes of colour in the hall. Messrs. W. Artindale had a striking group of the Red Hot Poker Mount Etna, a tall-growing variety of glowing orange scarlet. An excellent lobelia named Huntsman, with crimson flowers and very dark red foliage, was noted on this same stand. All the perennials shown by this firm were in good form. Two exceedingly fine large-flowered montbretias, Star of the East and His Majesty, were seen among Messrs. Daniel Brothers' collection of herbaceous plants.

Delphiniums and lupins were shown by several firms, and those exhibited by Messrs. Hewitts were of remarkable size and quality for a second crop. The best varieties—Joybells, Wembley and Violet Queen—seen on this stand were of the famous Wrexham strain. A varied and interesting collection of herbaceous plants was staged by Mr. T. Carlile. Lupin Sunshine, several delphiniums, heleniums, phloxes and asters were included.

Lobelias of a hardy hybrid strain in a great variety of colours were shown by Mr. B. Ladham. Mrs. Humbert, Purple King and Lady Gregory were all good. Border plants were exhibited by Mr. J. C. Case, and several fine snapdragons, such as The Fawn, Beacon, Empress and Carmine Queen, by the well known antirrhinum firm of Messrs. W. H. Simpson. Messrs. Forbes made an imposing group with pentstemons, dahlias and phloxes. Castle Forbes, a bright cherry red pentstemon with a white throat, was shown by them. Pentstemons were also shown by Messrs. Cutbush. Perennial scabious in many varieties was exhibited by Mr. Isaac House, and violas by Mr. W. Yandell. Herbaceous plants in general were also shown by Mr. G. Gibson and Mr. G. Jackman.

Lilies were seen on a number of the stands. The most interesting collection was that of Mr. Amos Perry, who showed lilies, watsonias, etc., raised from Empire-grown bulbs. The beautiful Lilium longiflorum giganteum, L. Regale, L. wallichianum superbum and Watsonia rosea were much admired.

Zinnias arranged by Messrs. Sutton and Sons formed an imposing group in the centre of the hall. Varieties of every colour were set out in a large circular bed. There were giant double varieties in shades of crimson, orange, rose and sulphur yellow; miniature pompon varieties in mixed colours, as well as double dwarf and double cactus flowered zinnias.

Phloxes of the herbaceous type formed one of the most important classes of border plants exhibited. The two largest collections were those shown by Messrs. E. F. Fairbairn and Son and Messrs. Blackmore and Langdon. Messrs. Fairbairn arranged large pillars of vivid-coloured phloxes in shades of purple, carmine pink and scarlet. Lord French, Vivid (a salmon scarlet), Sir Douglas Haig and Border Gem (a striking new deep blue variety), were perhaps the best. Mia Ruys (the finest all-round white phlox), Baron Van Heeckeren (salmon pink) and Nana cœrulea (a dwarf variety with a large mauve truss) were shown among Messrs. Blackmore and Langdon's collection. Messrs. Bakers had a charming soft pink variety named Apple Blossom, and Messrs. Forbes exhibited Rijnstroom, Albert Vandal and W. J. Marlow, all fine varieties.

MICHAELMAS DAISIES.

On nearly every stand of hardy border plants Michaelmas daisies predominated. Asters of every type were on show, but chiefly varieties of the amellus and Novi-belgi sections. King George and Ultramarine, both with the typical large blooms and dwarf habit of growth of the amellus section, were to be seen everywhere. Mr. W. Sydenham had a particularly good group

Digitized by Google

of this variety. All his asters were in good form. Fleuve Bleu and Mrs. A. H. Wiggin were two other amellus asters shown by him. Among the tall-growing varieties Mr. Sydenham had Maid of Athens and Grey Lady, while Rose McDonald, with heath-like foliage and tiny shell-pink flowers, was a most attractive variety of a different section. A fine collection was shown by Mr. E. Ballard, the aster specialist. Ruby Tips, one of the latest varieties raised by him, was exhibited. Its blooms are of an uncommon rose shade, and the buds as they open are a brilliant ruby red. Royal Blue (a rich purplish blue), Grey Lady (with its masses of opal grey flowers) and Countess (a rose-coloured aster) were a few of Mr. Ballard's best.

Little Pink Lady and Little Boy Blue are a charming pair of low-growing Novi-Belgii asters. The soft toned blooms of the former were seen on Messrs. Waterer's stand, and the latter variety with its semi-double deep blue flowers was exhibited by numerous firms, including the Chalk Hill Nurseries. Two of the best of the Novæ-Angliæ section (which includes strong-growing varieties with brightly coloured blooms produced in terminal clusters) are Barr's Pink and Lil Fardell. Barr's Pink is undoubtedly a very fine aster. It bears large bright rose pink flowers which have a showy gold and bronze centre. A conspicuous group of it was staged by the raisers, Messrs. Barr and Sons. Lil Fardell, with its rich clear pink flowers, was exhibited, among other asters, by Mr. H. J. Jones. Lavender (an early semi-double variety) and Charm (a soft pink aster) were also shown by Mr. Jones.

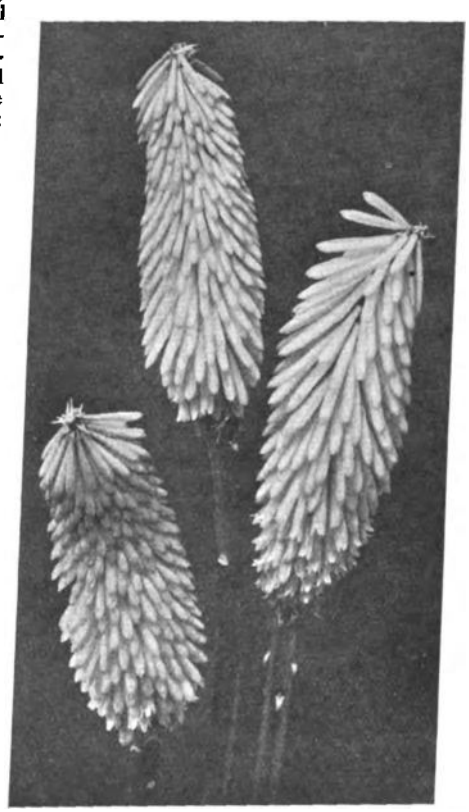
Messrs. Bunyard concentrated chiefly on asters of the amellus section. Beauty of Ronsdorf, lilac pink; Beauté Parfaite, the best of the dark violet shades; and General Pershing, with large pale pink flowers, softening to white in the centre, were outstanding. Mr. T. Bone staged a number of good seedling asters as well as a representative collection of modern varieties. Snowdrift, the finest semi-double white, was shown by him, and also Elsa, a good rosy lavender double variety.

ASTER RUBY TIPS, A NOVELTY IN MICHAELMAS DAISIES.

Messrs. Cutbush had an interesting group of perennials, and among them were the Michaelmas daisy Robinson V.C., of fine bushy habit, carrying long sprays of double mauvish blue flowers, and the distinct Aster Linosyris, whose dense terminal clusters of small rounded heads of golden yellow flowers have given it the name of Goldilocks. King of the Belgians (one of the tallest of asters), Cloudy Blue and Beauty of Colwall were three lavender blue asters shown by the Matham Gardens. Messrs. Baker, Messrs. Bowell and Skarratt, Mr. G. Reuthe, Mr. G. Jackman were some of the other exhibitors of asters.

CHRYSANTHEMUMS.

Considering the garden value of the early-flowering border chrysanthemums, it was a little surprising and, to some, disappointing, to find so few exhibits of them at the Autumn Show. Messrs. Puttridge Limited had



THE ORANGE RED SPIRES OF KNIPHOFIA MOUNT ETNA.

quite an imposing array of most of the best varieties, which they had massed in large stands. Their chief varieties were Mrs. Jack Pearson, bright orange varying to orange chestnut; Phœnix, a richly coloured flower of very similar habit and form; Hollicot Yellow, which is considered by many market growers to be the best early yellow, as it may be grown either as natural sprays or disbudded; Almirante is a bright red chestnut coloured flower; while Pink Delight and Cranford Cream need no colour description.

Undisbudded sprays were mostly shown by Messrs. Keith Luxford and Co., whose exhibit also showed the decorative value of the border chrysanthemum. They had large vases of T. Bannister, Miss Mattie and Cranford, three good yellows; Franfield Early, white; Lichfield Peach, Red Almirante, which is of more glowing colour than the type, and Provence, a pretty pink.

PHLOX BORDER GEM, OF A RICH DEEP BLUE COLOUR.

Good sprays of flower were shown by Mr. W. Yandell, who had Salmon Profusion, Phœnix, Dick Barnes (which has erect florets of wine red colour), Harvester and Mrs. Jack Pearson. Chrysanthemums were associated with other flowers by various exhibitors, notably Messrs. George Bunyard and Co., Messrs. Daniels Bros., and Messrs. H. Woolman and Son.

DAHLIAS.

Although there were many fewer new seedling dahlias than usual submitted to the Committee, the collections were magnificent and particularly numerous. Of the novelties which were selected for trial at Wisley, Irma found most admirers. It is of the useful miniature peony type and of rich vivid rose colour, with a small crimson zone. Maggie and Tibothe, which also were shown by Messrs. Burrell and Co., are of the same type and of orange buff colouring. The former is edged with rose pink and the latter is flushed with bright carmine.

In a magnificent group Messrs. Dobbie and Co. had brilliant stands of President Wilson, Dazzle, Amos Perry, Cactus and Crimson Flag, a neat double which should be valuable for bedding out. Their miniature peony and cactus varieties were also excellent. Mr. H. J. Jones again used his charming gilt baskets for colour schemes. The association of the maroon King Harold with the mauve Emma Groot, was very effective, and also was the scarlet and orange of Christine Prior and My Treasure. For bold effect no dahlias could be better than the glowing salmon of Jersey Beauty, while George Duncan of deeper colour is admirable. With nearly all his dahlias Mr. Jones used sprays of Michaelmas daisies of the Aster ericoides type, an association which also suggested itself to Messrs. James Stredwick and Son, who had delightfully arranged vases of their newer sorts.

Many were charmed with the hanging baskets and stands so well arranged by Messrs. Dickson and Robinson, who had many large decorative and small peony varieties. Show cactus varieties, such as Rachel Troughton, Pixie, Edgar E. Jackson, and Joyce Goddard were shown by Mr. J. T. West. Messrs. Jarman and Co. and Messrs. Carter Page and Co., while Messrs. W. Tresider, Limited, Mr. C. Turner and Mr. J. B. Riding had handsome blooms of Mrs. Warnaar, Emma

Digitized by Google

Groot, Mabel Lawrence and Couronne d'Or of the large decoratives. Messrs. J. Cheal and Sons, Messrs. H. Woolman and Son, and the Central Gardens Supplies had many good varieties.

SHRUBS.

Messrs. Hillier's exhibit housed a number of very interesting shrubs and trees, one or two of them on show for the first time, and it caused a considerable amount of interest among shrub enthusiasts. Two rare maples were on view; one, Acer Hersii, an arrival from China, with shapely and pointed foliage, and lithesome, red-coloured shoots; and the other, A. lævigatum, with Turkey oak-like leaves about 8ins. long, 1¾ins. broad and a serrate margin. A touch of colour was provided by a fine standard of Pyrus Vilmorinii, covered in berries, and the tinted foliage of Vitis Thomsoni and Himalayana and Acer circinatum. The whitewashed stems of Rubus Veitchii stood out well against the more sombre colouring of many conifers, including the fox tail-like Larix Potanini, Cunninghamia sinensis and Picea polita. A new buddleia of B. Farreri Kingdon Ward's, 6372, with very woolly leaves and small racemes of small violet flowers, looked to be a welcome addition to the genus, but judging from its nature, it may prove a difficult "doer" in gardens other than in the south.

Many other interesting plants were included among them the black-fruited Cornus Controversa Cotoneaster Dielsiana applanata and the handsome Pyrus aria majestica.

An admirable collection of hollies, both variegated forms and species, backed by a number of conifers and berried shrubs, was shown by Messrs. John Waterer, Sons and Crisp. Neat little bushes of the pink-fruited Pernettya murcronata were most attractive, while the coral-pink rounded drops of Euonymus Yedoensis caused much comment. It is a most handsome shrub in autumn and deserves to be much more widely grown. A few well flowered hibiscus were also shown. Unfortunately, however, these are only suited to southern gardens. They refuse to face the more rigorous climate of the north. The sea buckthorn was there and a number of berberis and cotoneasters, all well berried, but with, as yet, little colour.

Messrs. Cuthbert grouped a number of ornamental forms of cupressus and retinospora with lilies, the association is a most charming one as well as illustrating how lilies are best grown. One of the best was the elegant Cupressus Allumii. Another firm who also had a mixed exhibit of shrubs and herbaceous flowers was Messrs. Wallace. Here a fine collection of well tinted Japanese maples was staged in addition to the thorny Ilex Veitchii, carrying a crop of berries.

As is their custom, Messrs. Cheals again staged both an attractive and interesting exhibit. Cotoneasters acutifolia and moupinensis were both on view, the latter with viburnum-like leaves and carrying a heavy crop of rich red berries. The decorative Crataegus Warleyensis, with its long oval leaves and its loose clusters of small reddish fruits was there, along with the red-coated Berberis Thunbergii and the curiously tinted Prunus Hersii.

Mr. G. Reuthe showed a number of interesting things in which we noted Eucryphia Moorei and K. Billardier.

Almost opposite was Mr. R. C. Notcutt's group, worthy of every gardener's attention. Every year Mr. Notcutt stages a variety of subjects and this year his exhibit was even more representative. Quite a number of autumn flowering subjects were shown, including Perovskia atriplicifolia, Hibiscus in variety, Clerodendrons Fargesii and trichotomum, Thalictrum dipterocarpum and Weigelia Abel Carriere. Berried shrubs were plentiful and included Hypericum hircinum grandiflorum, a most decorative shrub, and its relative, H. androsanum, with black fruits. Cotoneaster Zaballi Henryana, frigida and Berberis Corii. It was a group indicative of what our modern shrubs are capable of providing in the way of decoration in the garden.

The other exhibitors were Messrs. Robt. Green and Co., who staged standard bay trees; Messrs. Orpington Nurseries; Hollamby's Nurseries, with a number of maples and cotoneasters; Messrs. Charlton and Sons; Messrs. Fletcher Bros.; Mr. Geo. G. Whitelegg, with rock garden conifers; and Messrs. Harrods and Mr. Klinkert, with exhibits of topiary work.

ROSES.

The popularity of half a dozen or so of the newer hybrid tea varieties with the growers was fully evident, for nearly every exhibit contained beautiful blooms of the brilliant Lady Inchiquin, Shot Silk of shining elusive colouring, the dark fragrant blooms of Etoile de Hollande, the deep pink Mrs. Henry Morse, Golden Emblem of rich colour, and either Ophelia or Mme. Butterfly of chaste colouring. These may well be termed the roses of the Show, for they appeared everywhere.

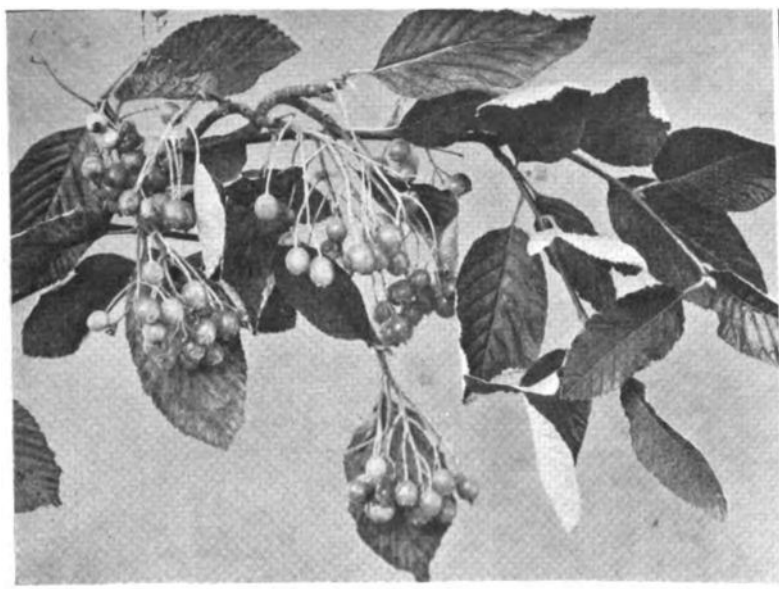
At this season new roses were, naturally, not expected in any quantity, but Messrs. Alex Dickson and Sons had a splendid basket of Dame Edith Helen, which, besides being the most fragrant new rose, has every other merit of the desirable rose. Few varieties, if any, dazzled the visitor more than Angele Pernet, especially as seen in Mr. George Prince's pillar, where its orange glow, occasionally flushed with peach pink, was irresistible. In addition to the charm of colour, it is sweetly scented and said to be very free-flowering. Messrs. Wood and Ingram had a large arch of this variety.

White Ensign, Margaret McGredy, of rich scarlet crimson colour, and the Golden Florence Izzard in the gold medal group of Messrs. S. McGredy and Son, were excellent. Besides Angele Pernet, Mr. Prince showed Padre, which even when full blown is of gorgeous colour. Windsor, a fully double crimson rose, shown by Messrs. Chaplin, Bros., appears to be a good bedding variety. Their blooms of the large single Mermaid, which has such lovely golden stamens, and the equally large Innocence, were very fascinating.

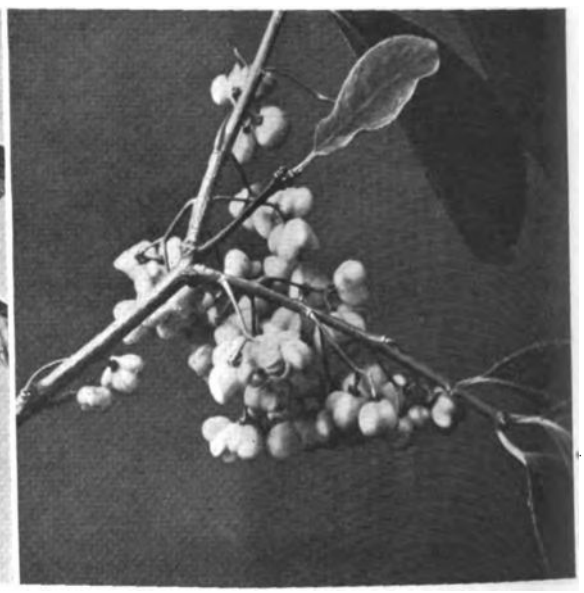
Clovelly is an excellent large, pink hybrid tea, and Mr. Elisha Hicks had two beautiful baskets of it with Joanna Bridge and the fragrant General McArthur near by. G. H. Mackereth, which Mr. John Mattock has shown several times this year, was again of great merit. As befits a rich crimson rose, it is deliciously fragrant. Chief of the fragrant roses shown by Mr. Walter Easlea were Etoile de Hollande and Hadley.

Cecil, a rich yellow single rose of large size, was excellent in the group of Messrs. B. R. Cant and Sons, who also showed the fragrant blush coloured Mrs. Beatty. Messrs. Wheatcroft Bros. had a gorgeous basket of Los Angeles and unusually good blooms of Mrs. Charles Lamplough.

There were many varieties of the free-flowering dwarf polyantha and of the pillar roses. Messrs. A. Warner and Son set up well filled vases of Mrs. W. H. Cutbush of beautiful pink colour, the rich reds of Jessie and Koster Orleans and the pink Ellen Poulsen. Kirsten Poulsen, of rich scarlet colour, with deep rose pink Alice Amos, shown by Messrs. D. Prior and Son, are good examples of the larger-flowered polyanthas.



PYRUS ARIA MAJESTICA, WITH HANDSOME FOLIAGE AND BRILLIANT RED FRUITS, SHOWN BY MESSRS. HILLIER.



THE CORAL-PINK ROUNDED DROPS OF EUONYMUS YEDOENSIS, SHOWN BY MESSRS. WATERER.

Digitized by Google

while Variety and Pax, as shown by Mr. J. H. Pemberton, are more vigorous varieties which produce large quantities of bloom.

GLADIOLI.

Along the front of their handsome groups of gladioli, Messrs. Austin and McAslan had dainty bowls of Lady Bethune' a lovely pink variety; Orange Brilliant, Loriot, Atalanta and L'Exuette. Among their large-flowered sorts Red Emperor, Red Canna and Princeps were of rich glowing colour. Golden Measure, the smaller richly coloured King Christian, Orange Nassau and the purple Baron Hulot were very handsome.

Primulinus varieties, including Asia, Alice Tiplady and Rosanra were included by Messrs. R. H. Bath, Limited, in their extensive group of gladioli. Their large-flowered varieties included Red Canna, Miss Spokane, Lucette and Red Emperor.

A valuable selection of both types was attractively arranged by Mr. Alfred Edwards, and Messrs. Lowe and Gibson, set out a number of their well coloured seedlings, with a background of delphinium spikes.

STOVE AND GREENHOUSE PLANTS.

Even those whose garden interest is centred in hardy flowers could scarcely fail to have been impressed by the handsome crotons shown by Mr. A. P. Brandt of Bletchingley Castle, Surrey. Every one of the many plants was a model of first-class cultivation, and the shining leaves of golden and green, of crimson, golden and green colour, and of many forms, made the exhibit of great decorative value.

The large leaves of the caladiums, in a well arranged group of stove plants by Messrs. John Peed and Son, gave colour and tropical luxuriance of quite a different type. Many of these immense leaves were of such delicate and transparent loveliness that it seemed almost impossible that they could withstand even the most gentle breeze, while often these fascinating leaves had so little green in them that one marvelled how, in Nature's scheme of plant life, they grew and were so healthy. Besides these caladiums, Messrs. Peed showed well coloured crotons and a fine strain of the greenhouse streptocarpus.

The fragrant Bouvardia Humboldtii corymbiflora, with the smaller flowered sorts, which a few years ago were in great demand as buttonhole flowers for gentlemen's evening wear, were associated with the greenhouse Erica gracilis, E. nivalis and the pretty rose coloured Chironia exifera by Messrs. Stuart Low and Co., who, at the back of the group, had gorgeously coloured cannas.

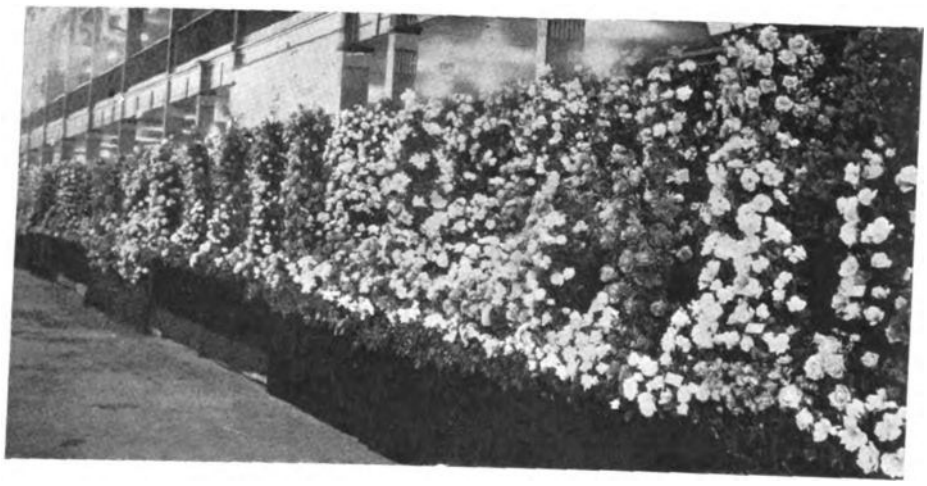
The stately New Zealand tree ferns which Messrs. T. R. Russell, Limited, grouped so well on mounds made a splendid centre for the floral groups in the hall. Beneath the Dicksonias and cyatheas they cunningly placed Sansievieras marantas, Billbergias and foliage begonias, which gave a fascinating exotic effect.

Messrs. Blackmore and Langdon are famed for the excellence of their double flowered begonias, and on the present occasion they seemed to have excelled even their own high standard of excellence.

There was only one group of cacti and allied plants, but Mr. Sydney Smith showed this bristling and peculiar race of hot, dry-country plants in great variety and to perfection.

In Messrs. Carter's handsome circular group there were many splendidly grown plants of the gorgeous Clerodendron fallax with many useful liliums and dwarf everflowering begonias.

A description of the Orchids and New and Rare Plants will be found on page viii of this issue.



LOOKING DOWN THE ROSE AVENUE.
One of the best rose displays ever seen at Holland Park.

MESSRS. AUSTIN AND MCASLAN'S EXHIBIT OF GLADIOLI.
The elegant spikes of these handsome primulinus hybrids were in splendid condition for so late in the season.

THE FRUIT AND KITCHEN GARDEN

Lifting and Storing Maincrop Potatoes.

GARDENERS and farmers, as well as seamen, take due note of the prevailing weather conditions—current signs throughout the year. When the weather is fine harvest work is rendered more pleasant, and the crops, gathered in such circumstances, are all the more likely to remain in a sound condition for a longer period. The maincrop potatoes are, generally, dug, sorted and stored during the month of October. Very often we experience really good weather in this month, and, while such ideal spells continue, we should lift the tubers, dry and store them. When the garden fork is used, some of the tubers get stabbed unless great care is taken. Instead of driving in the fork between the haulm and roots, insert it at the side of the ridge, driving it in well under the roots, then throwing out the latter so as to free them from soil. The tubers should be graded when they are picked up, to obviate the necessity of too many handlings. The large, medium-sized and small tubers should be placed in separate flat-shaped heaps, preferably in an open, cool shed facing the north. In such positions the tubers should remain for about one week, being turned over once so that any tubers that may be decaying can be picked out before they contaminate sound ones, as they would if placed with the latter in the store heap. The ground is afterwards forked over to expose tubers left buried. Some are sure to be damaged, and all such ought to be stored by themselves for immediate use.

When storing the tubers in sheds, be sure that, in the case of wooden floors raised from the ground, there is an ample thickness of straw under them as well as against the walls, especially outer walls, as frosts penetrate quickly and, unlike top coverings, side ones cannot be easily applied to the heaps.

Outside potato clamps should always be arranged on high, dry ground, the actual bed of the heap being higher than the ground surrounding it. The ideal way to cover the heaps is first to place straw next to the tubers, then ordinary soil and litter, and dry fern or similar short material as an outer or final covering, with wisps of straw at about 4ft. apart fixed near the top of the ridge for ventilation. The ridge should be at an angle of 45°, then rain-water will readily run off.

When Picking Fruit.

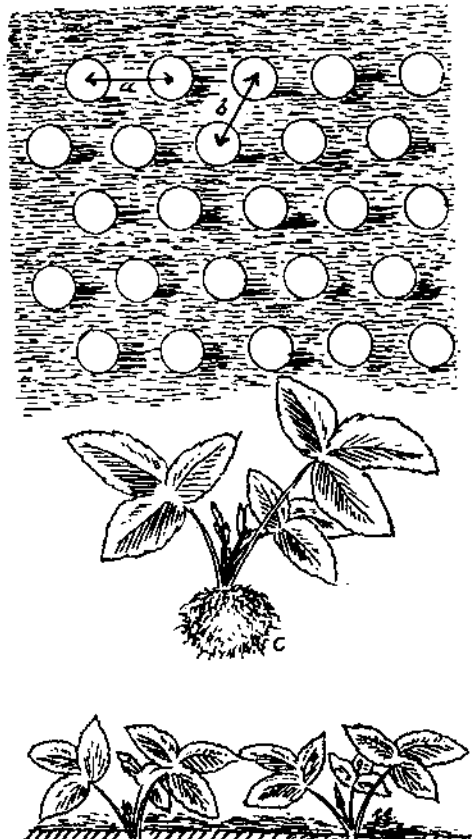
WHEN gathering apples and pears it often happens that some of the fruits tumble to the ground. This causes bad bruises likely to impair the keeping qualities of the fruit. With small trees, or those of moderate size, the following is a good plan: Get a large dust sheet, or any similar piece of material, and arrange this under the branches of the tree. The sheet should be kept some inches clear of the ground by tying it at the corners to wooden stakes. Then, any fruit that tumbles will fall into the sheet instead of dropping on the hard ground.

Earthing-up Winter Greens.

THE drawing up of soil to rows of winter greens has a very beneficial effect, especially if the work is done in good time before the leaves have become very large and entirely closed up to the space between the rows. The first to be dealt with should be the Brussels sprouts, those raised from seeds sown last autumn. In their case the roots will have taken possession of most of the soil, so that only the portion from the centre of each space between the rows of plants should be utilised for placing over the roots and against the lower part of each stem. In the case of July-planted greens more soil should be heaped against the stems, especially against the stems of broccoli, as it is the portion of stem immediately under the lower leaves that is the tenderest part, and suffers most when severe frosts come. If the ground is dry apply water, and then draw up the soil high enough to touch the lower leaf-stalks. Use the Dutch hoe where there is ample room to do so without breaking off the leaves. Where the leaves almost meet across the space use the spade on light and the garden fork on heavy ground.

Planting Late Strawberries.

IT is not always possible to procure runners early enough to permit of the final planting out in July or during the early part of August. The bulk of the runners are available for planting in September.



Of course, early planting means established plants before the cold days of winter come. Late planting means that extra care must be taken when the work is done so that the check to growth will not be serious.

Some cultivators do not attach much importance to the matter of soil enrichment, relying mainly on mulching to supply nutriment to the plants. But I believe it is very beneficial to the plants if they are at first grown in a really good soil, then the mulching will be a supplementary assistance, and can be applied in weak or strong doses, according to the condition of the plants at the time. All soils should be trenched 2ft. deep for strawberry growing. The plants certainly do well on a medium heavy loam well worked. They also succeed splendidly in a sandy soil. The latter is mainly composed of tiny stones and the soil about 2ins. below the sufrace is always moist in very hot weather. Planting in a sandy soil rarely checks growth, however late the work may be carried out.

The approximate distance from plant to plant in the rows should be 18ins. and the same distance from row to row as shown at *a* and *b* respectively. A properly rooted young plant is shown at *c*, the wrong way to plant at *d* and the right way at *e*. A trowel is the best tool to use.

Thinning-out Raspberry Canes.

RASPBERRY plants that do well, that is, grow freely in a good soil, are often neglected as regards the due thinning out of surplus canes. The best time to do this work is immediately after the fruit is gathered; the worst time after the winter has passed. The canes retained should be exposed to as much air and sunshine as possible so that they will become hard and well ripened before the dull days of winter come. Also, throughout the wintertime air does much good to well thinned canes. Now, the cultivator should understand all about the quality, good or bad, of the canes. Those who have not had much experience will not thoroughly understand, and the hints here given will be helpful. A cane that is very thick and very tall is not an ideal one. One that is weakly, dwarf, with a thin and pointed top, is also a poor specimen. The one of medium height, or just above medium height, of good average thickness and with leaf-joints rather close together is the kind to retain. First cut out to the soil level the weakly shoots, then deal with the very strong-looking ones—they are, usually, sappy or very pithy—and finally deal with the medium-strength specimens. Rows: If the plants are grown in rows and are tied to wires, a fair average distance apart from cane to cane at the final thinning will be 7ins. or 8ins. Clumps: If the plants are grown in clumps, four or five canes will be sufficient to retain in each clump. The retained canes in both cases will be benefited if they are left untied until the end of November.

The New Asparagus Bed and How to Make It.

EVERY amateur who possesses a vegetable garden likes to have it well filled with healthy produce, and the asparagus bed is generally the one that claims most attention when it comes to the making of it. If the position is one on a gentle slope, beds should be formed at right angles to the fall of the ground so that all the rain-water possible will be retained for the benefit of the roots. And when manure water is applied, it, too, will not run away and be wasted. The planting and the sowing, whichever is preferred, should be done in the spring, but the bed ought to be got ready during the autumn months so that the soil will be in prime condition just when it is required for use.

Some cultivators put in a lot of manure and bury it deeply; this is the wrong way. The soil should be trenched quite 2ft. 6ins. deep, and the manure used, well mixed with the soil, about 9ins. below the surface, then the plants will in due course derive benefit from it. Deep trenching is very essential to success. The bottom portion should be well broken up, but left below; the top portion should be left in a rough state. It does not matter how lumpy the soil may be, as the full exposure to the weather during the winter will be beneficial. Air, frosts and rains will pulverise and sweeten the soil a great deal. A bed should be large enough to accommodate three rows of plants 20ins. apart, leaving a space of 12ins. on each outer side.

GEO. GARNER.

A COLD HOUSE IN EARLY AUTUMN

The keen amateur will find a small unheated greenhouse an immense asset to the successful stocking of his garden, as well as providing a brilliant display of easily grown pot plants during the spring months.

IT should be borne in mind that an unheated greenhouse depends entirely on sun heat; consequently, there will be periods when it will not be possible to keep out frosts. This fact puts out of court a large number of plants that may be grown in greenhouses from which frosts are just excluded. Still, we have plenty of material available for our purpose, the majority of the plants being hardy, or nearly so. At present, the house may be filled with tomatoes, and, having picked the fruit, both green and ripe, the old plants should be cleared out and burnt, if only to put an end to thousands of eggs of the white fly.

Numerous annuals, like balsams and Lobelia tenuior, will be over, and the indispensable tuberous-rooted begonia will now require drying off till the spring. When the tubers are quite at rest, they should be shaken from the soil and stored in a dry place which is safe from frosts. All climbers should be cleansed, pruned where they are crowded, and then tied up so that they do not exclude light. A large number of climbers ought not to be encouraged, but one or two may be allowed, with pleasing results; while a back wall is greatly improved and made profitable when covered with a rose or other plant. Among the roses will be found Scarlet Climber, Gloire de Dijon and various climbing hybrid teas; while the beautiful white, scented Mandevilla suaveolens should be included, and, where it is possible to plant it out, Diplacus glutinosus ought to find a congenial home. Cassia corymbosa is also recommended. Any climbers could be planted at the present time, and, although little top growth will be made, the roots will be making headway ready for the spring.

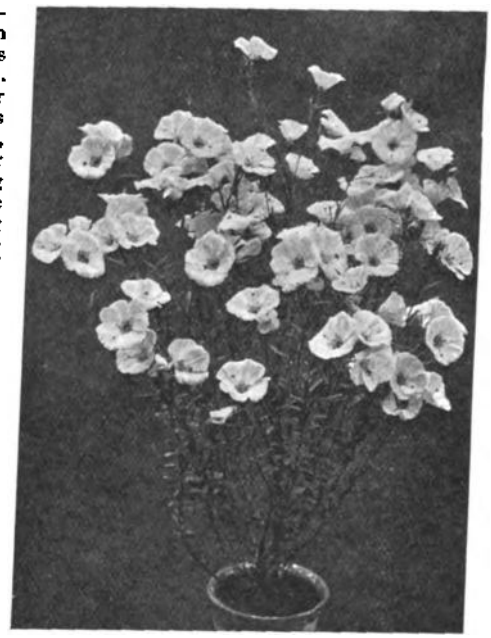
Throughout October, November and the greater part of December, if the weather proves open, a good display of chrysanthemums can be obtained. These have been growing in the open, and now the earlier-flowering sorts must be taken inside, first picking off dead leaves, and carefully looping up the growths. Here a note of warning is necessary to the owner of a small cold greenhouse: more attention must be paid to ventilation, and when the chrysanthemums are inside, leave all the ventilators open to their fullest extent, and even the door when there is little wind.

With care, Primula stellata can be grown, also the bright yellow P. kewensis, and these should be placed on the side stages. Fuchsias can be stood under the stage till the spring. Most greenhouses possess a shelf, and this can be filled with pots of schizanthus, stocks, and clarkia (but these must be kept slightly on the dry side until the spring), godetia and salpiglossis.

Roses in pots offer scope for the observant grower, and with the selection of suitable varieties a fine display can be obtained some weeks in advance of those outside. If already established in pots, so much the better, and now they should be overhauled, top-dressed with good quality loam and the drainage put right, but not pruned until taken inside some week hence. A start could be made by potting up some new bushes during the next few weeks, afterwards plunging the pots in ashes until after the beginning of the New Year.

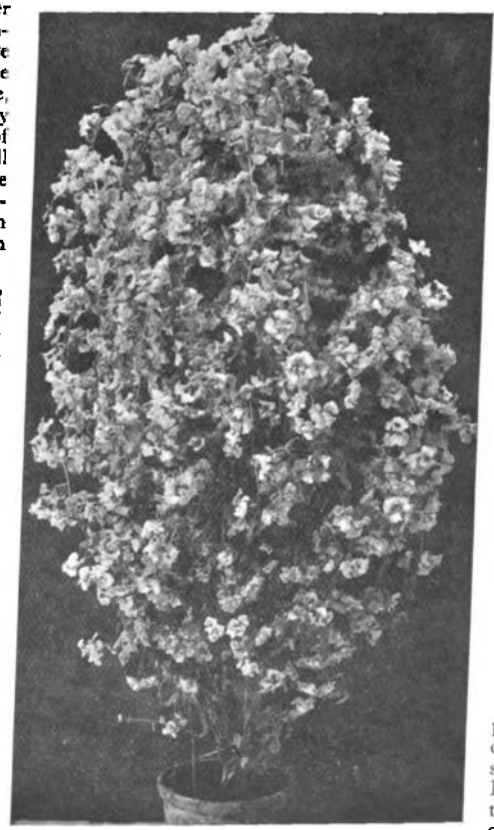
Bulbs and Tubers for the Cold House.

These ought to play an important part in keeping the house gay after Christmas and bridge the interval between late chrysanthemums and stocks, and they ought to be potted



GODETIAS ARE ADMIRABLE FOR GREENHOUSE DECORATION.

at once. Receptacles 5ins. to 7ins. in diameter are suitable, and when the repotting is completed, plunge the pots in old ashes to a depth of several inches until root action is well advanced; then they are moved into the greenhouse. Among the bulbs suggested are narcissus, tulips, hyacinths and others quoted in most bulb catalogues. Freesias can be potted, also the beautiful Iris tingitana, whose large bright blue flowers can be had soon after Christmas. Solomon's Seal and lilies of the valley, Christmas and Lenten roses, Iris reticulata, I. Histrio and I. Danfordiæ are choice plants, and very effective in pans 8ins. to 10ins. across. Most of the lilies are suitable, especially the glorious L. regale, which is readily raised from seeds. It is both an ideal border and pot plant, and when employed under the latter heading the bulbs should be potted up now, and sparingly supplied with water during the winter months. L. tigrinum splendens, L. croceum, L. candidum and L. longiflorum may be afforded similar treatment.



A FINE PLANT OF CLARKIA.
Seeds should be sown now.

In the spiræas or astilbes, we have a graceful lot to choose from, the pure white variety Gladstone, and Peach Blossom, with its large feathery sprays of blush pink flowers, are both good, and this remark also applies to S astilboides. The early-flowering Scilla sibirica will furnish blue colouring, and ixias, beautiful bulbs from the Cape, are rather out of the ordinary, and six bulbs in a 5in. pot will create considerable interest. The early-flowering gladiolus, of which The Bride may be cited as an example, are all worthy of consideration by the owner of a cold greenhouse.

Shrubs for the Cold House.

Early-flowering shrubs will produce quite a fine display in the early spring, and a few should certainly be grown. Many of them can be secured already established in pots, but they may also be lifted from the open ground and potted up in readiness to arrange in the house directly space is available.

One of the best shrubs for our purpose is Forsythia intermedia spectabilis, a golden yellow, free-flowering plant. Deutzias are also excellent, while lilacs, both the coloured and double white forms, are always appreciated. Azaleas, especially the mollis group, are showy; and small, well budded examples of rhododendron will repay the trouble in potting them up. I have found both the double and single flowered philadelphus a great success, also well established specimens of Jasminum primulinum.

The sweet-scented Viburnum Carlesii is a gem, and, if space is available, the laburnum can be included. Small plants of Wistaria sinensis, especially grown for pots, will bloom freely under glass; while Staphylea colchica is a white-flowered plant worthy of consideration.

The extent of the structure and the taste of the owner will decide the number of shrubs grown, and it should be borne in mind that the list of names submitted above can be extended considerably, for there is to-day a wealth of fine material for the gardener to choose from.

The earlier the above are potted up the better, and then they may have their pots plunged in ashes till needed. This will keep the roots uniformly moist, and help to prevent any frosts splitting the receptacles.

Alpines for the Cold House.

I merely draw attention to this delightful phase of gardening, but, with many of the choicer subjects, it takes years before one secures such glorious specimens as seen at Kew, and a few other establishments. Nevertheless, the possessor of a cold house might give the matter a thought, and in the meantime begin to get a few plants together.

T. W. BRISCOE.

WHAT OUR READERS SAY

A SMALL TOWN GARDEN.

SIR,—I was much interested in Miss Jekyll's admirable article, "The Joy of Making a New Garden," which appeared in last week's issue of THE GARDEN. Such a series of articles and plans should prove of great assistance to those finding difficulties in the way of laying out and planting a garden in the suburbs of our large cities and on the outskirts of our country towns. In connection with this I thought the two accompanying illustrations might be of interest to readers to indicate to some extent what can be accomplished even in the town. Full use has been made of the space and by a judicious blending of stonework and plants quite an effective town garden has been made. The photographs may indicate to others who find themselves in a similar position a certain line of treatment of their space which they will find to result in a charming garden.—C. T.

[We should be pleased to receive notes and illustrations of any of our readers' gardens with a view to their publication. Such notes and illustrations are always of interest to others, as they bring up new points and raise new questions.—ED.]

A CHARMING VISTA IN A SMALL TOWN GARDEN.
Borders of herbaceous flowers set off by brick paths make a pleasant combination in such a position and in limited space.

THE LORETTE SYSTEM OF PRUNING.

SIR,—May I ask, through the columns of your valuable paper, if any of your readers can tell me anything about the Lorette system of pruning for pears and apples. I have read something about it, and it seems to give wonderful results in France; but I should very much like to know if there is anywhere where it has been tried in this country, and, if so, with what degree of success. Thanking you in anticipation.—G. C. O.

A PENTSTEMON WHICH SHOULD BE MORE GROWN.

SIR,—That this species (P. gentianoides), which is rarely met with in cultivation, has possibilities for garden decoration is evidenced by the admiration that a bed of it near the tropical ferneries at Kew excites.

It is a native of Mexico and produces its spikes of delicate mauve coloured flowers with great freedom from mid-July to October.

Propagate from cuttings inserted in a cold frame in September. When rooted, admit plenty of air on all favourable occasions and plant out in a deeply dug nursery bed into which some leaf-mould has been worked, in early April.

When the spring bedding plants have been removed from the beds the pentstemons may be planted at a distance of one foot apart. Pentstemons delight in a sunny position and a deep, rich, well drained soil. Liquid manure applied at intervals during the summer is decidedly beneficial.—T. H. E., *Kew.*

THE BOUNDARY OF THE GARDEN WITH TRELLISED WALL.
This end screened portion may serve in summer as an outdoor dining-room.

PLANT COLLECTING.

SIR,—I was very interested in Mr. C. Elliot's note, in your issue of September 4th, on "Phyteuma comosum, as during a walking tour in the Dolomites this summer I kept a perfunctory look-out for it, but without success. As I was there in June and the season was very late, presumably I was too early to find it in bloom. My object in writing you, however, is to obtain some information as to the best way to get plants over from Italy. Farrer, in his work on Alpines, says remove every particle of earth from the roots and pack dry in tin boxes. This, under ideal conditions, is, no doubt, sound advice. The difficulty is, though, that one often is compelled to get the plants up when the ground is soaking wet, even if, as is not always the case, the atmospheric conditions are favourable. Then, again, the parcel post from Italy takes about a week on the journey. The result in my case was that tins of cherished roots arrived at their destination as wet and decomposing masses. I intend visiting the Dolomites again next summer, and am anxious not to repeat this year's disastrous failure, so I should be very grateful to Mr. Elliot or some other expert if he would give your readers a few hints on this subject, which, I am sure, would be much appreciated by many, who, like myself, delight in enriching their gardens with some of the many lovely and fascinating plants that they come across in their travels abroad.—C. RUNGE.

PRUNUS DAVIDIANA.

SIR,—Now that the planting time is coming near once more, I should like to recommend everyone who has not done so to put in one of these most attractive little trees. I planted mine about six years ago, and it has done very well in a rather unprotected position, where it must certainly get a good deal more than one would choose of the keen spring east winds which never fail my garden.

Digitized by Google

Also, as it was placed quite near the boundary fence, it has suffered a good deal from the admiration of passers by, and has been practically beheaded twice. This seemed tiresome at first, but the little tree seems really to thrive under the treatment. The soil is a fairly good clayey loam, and it gets an occasional sprinkle of lime, but otherwise has no attention. It is always out early, and just over when the almond comes into bloom, so it is a real treasure in the beginning of the year. My specimen has pure white flowers and the petals are of a very firm substance and stand a good deal of bad weather. I hear there is a pale pink variety, but have never seen it. It is said to grow to 20ft., but mine does not seem likely to be so tall. It has a more upright habit of growth than many trees, so does not take very much room.—A. E. W.

THE STAR FLOWERS.

Plant Them Now.

SIR,—Now is the time to plant these dainty and pretty spring flowers. They love the shade of the woodland, and should be planted with plenty of leaf soil. The starry flowers are small, and white or pink in colour; they grow in clusters on slender stems from 9ins. to 18ins. high, and are surrounded by a collarette of small pointed green leaves. It is a curious little plant, its calyx is seven parted, the flowers have seven stamens, and usually its little collarette is composed of seven leaves. They flower in April and May and die down in early autumn, after the manner of trilliums. They have a creeping, woody rootstock, and are best propagated by seed sown in the spring and root division in the autumn. Trientalis are of the primrose family and are easily grown. T. americana, arctica and europæa are the principal species.—R. MOORE, *Thorpe Hall.*

VIBURNUM RHYTIDOPHYLLUM.

Is it a Shrub Worth Growing?

SIR,—In spite of the praise bestowed on this viburnum by Mr. John Hill, it is nevertheless a disappointing subject in the majority of gardens. It is often a ragged, untidy plant, and why it ever received a first-class certificate from the Royal Horticultural Society I do not know. The chief beauty and attraction of V. rhytidophyllum is undoubtedly the clusters of red and black fruits which appear at their best in autumn and early winter, if we are lucky. These, however, are rarely seen, as the flowers fail to set. If this could be overcome, the plant under notice would be of some value and merit. This winter, however, I hope to plant up an example of the native V. lanatum in close proximity to V. rhytidophyllum, as I have been told that it is necessary to secure fertilisation of the flowers of the latter species. Perhaps some other readers have tried this experiment, and, if so, the results obtained should be made known to readers of THE GARDEN. As a foliage plant I cannot recommend V. rhytidophyllum, but as a berried shrub it is useful, providing it is possible to obtain a good crop of fruits.—T. W. BRISCOE.

[We should be pleased to hear from readers who have tried growing these two plants in association for fruiting purposes.—ED.]

HINTS WORTH REMEMBERING

This is the second instalment of Hints that have been received from our readers in response to our request. There seems little doubt, judging from the numbers that have reached us, that this will prove a most useful feature of THE GARDEN *in future. We hope, therefore, that all our readers will assist to make this page as valuable as possible by sending in their Hints, the result of personal observation and trial, and so help the gardening public in general. Hints which will be specially considered as worthy of a prize will be those that are seasonable as well as interesting and apply particularly to duties that can be carried out in the garden at the present time.*

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Each must be sent in on a separate sheet and must not be more than 300 words in length.

THE HALF-GUINEA HINT

An Effectual and Economical Method of Spraying against Mildew.

Procure a sheet of corrugated iron, large enough to accommodate a pot chrysanthemum lying at full length. Fix it at a gentle slope, one end resting on something higher than the other. Lay the infected pot plant upon it, and syringe first from one end, then from the other, gently rolling the pot over as you proceed, so as to ensure every part of the leaves—underside as well as top—being reached by the spray. If a small tank or footbath be placed below the lower end of the corrugated iron sheet, the spraying mixture drains into it, and can thus be used again.—D. H. P.

Use Your Old Broom Heads.

When my brooms are worn and no further use for sweeping purposes, I have found them most useful as a bootbrush and scraper, either at the greenhouse or potting shed door. To form this I simply drive two short stakes into the ground, leaving about 4ins. or 5ins. above the ground. Then I nail the broom head on to these, and I find this method saves a lot of dirt and grit from treading into either greenhouse or potting shed, as one can clean both the sides and the bottom of the boots.—T. S.

A Handy Tool.

For those who find difficulty in hoeing among the roots of crops and herbaceous plants, a very useful tool can be made by putting a 4ft. or 5ft. handle on to an ordinary weeding fork, one with narrow prongs for preference. The surface of the soil can be effectually broken up without any danger of cutting the roots of the plants. Also it will be found handy for weeding, in that it saves stooping, and the back of the borders can be reached without trampling on the front of the beds.—L. P.

Weeds on Lawns.

Tap-rooted weeds in lawn or garden can be completely eradicated if, when the tops are cut off, a wooden skewer, previously dipped in crude carbolic, is pushed home. It is recommended that an old pair of gloves be worn, but a cork near the blunt end of the skewer will prevent the fluid reaching the fingers.—E. E. P.

Forget-Me-Nots for the Cold House.

I wonder whether many people have tried growing forget-me-nots in pots to flower early in spring with the first bulbs. Last spring I grew forget-me-nots in pots with great success. Potted up in October, they remained all winter in a quiet corner of a cold conservatory, requiring little attention, only needing water occasionally and soot-water once a fortnight until the flowers began to show. They were then brought to a sunny shelf, and when they finally flowered, were plunged in a bed of snowdrops, the effect being fresh and charming.—D. S. D.

Try Sphagnum Moss for Difficult Subjects.

Androsaces and primulas thrive in sphagnum, without soil, on the shelf of the little cold greenhouse. Try it mixed with a little peat and leaf-soil in pockets to grow our native plants from damp places on the hills. Try it for the difficult primulas in gardens where there is no "water's edge" to plant them by. Primula farinosa planted in July in a small trough in a hot, dry, exposed place in sphagnum, with a little leaf soil below, has flowered through August into September.—M. G.

Shrub Cuttings.

Instead of putting in ripened cuttings of deciduous shrubs in autumn, wait until late spring or early summer, when the plants will have made 2ins. or 3ins. of young growth. From these shoots make cuttings, and insert them in sand in a cold frame or box and cover with glass. Except for wiping the moisture off the glass each morning, keep close for about three weeks and shade from the sun. Cuttings should be "calloused" by this time, and air may gradually be admitted until fully open. In from six to eight weeks they should be put into thumb pots. Pot in a mixture of one of leaf mould, one peat and two parts silver sand. Give the pots a good soaking of water through a fine rose. Place in a frame, and shade from the sun. Cletharas, staphyleas, cornus, caryopteris, etc., may be grown as above.—W. G.

Gentiana Verna.

I have found the following method of growing the above very effective: Grow in 3in. to 4in. pots in compost of good fibrous loam and sand. Plunge the pots in sand below the ground level so that the plants may obtain all the moisture possible, preferably at the base of the rockery. In spring top-dress the crowns with sandy soil and limestone chips. My small plant in a 3in. pot had nine beautiful blooms under this treatment last spring.—T. A. T.

Plants for Hanging Baskets.

My kitchen has two windows. All summer I have kept them gay with hanging baskets lined with moss. A creeping campanula provides the green background. About once a week—perhaps twice during very sunny, dry weather—I soak the baskets thoroughly with water. I then secure showy trusses of schizanthus and stick the stems well down in the wet earth, above and below the basket, so that the effect produced is like a ball of blossom. I find that schizanthus lasts fresh in this way for a fortnight, if the dead blooms are picked off and the earth kept wet. I have used hard wooded sprays of clarkia with equal success, and I feel sure that many annuals would lend themselves to the scheme. Thus one avoids monotony, nor has one to wait with patience until the planted flowers in the basket bloom.—M. W.

Digitized by Google

GARDEN PESTS AND HOW TO DEAL WITH THEM

THE gardener has always to combat the enemies of his crops. He sows, he plants, and directly the young plants appear above the soil they are attacked. Often before they pass the stage of the seed leaves they are destroyed. The crops when

Eggs of the large white cabbage butterfly greatly enlarged.

The very young larvæ of the cabbage butterfly work in companies and are relatively easy to collect and destroy. This is one of the worst enemies of the garden.

half-grown are not exempt from attack, neither are they when they are approaching maturity.

The Cabbage Butterflies.

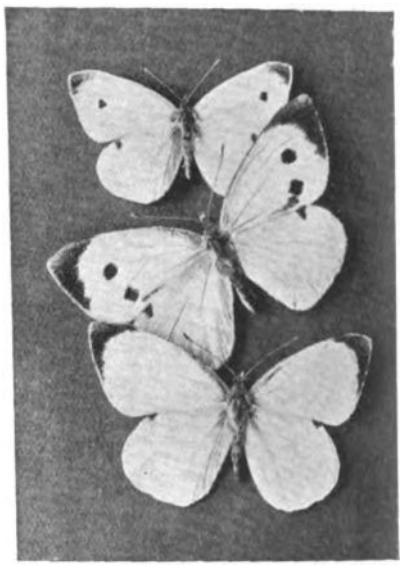
Both large and small cabbage butterflies are now attacking the plants. The large white butterfly lays its eggs on the undersides of the cabbage leaves, and are so hidden from view that the caterpillars resulting are swarming over the plants before we are aware of them. It is too late to stop the fly laying its eggs, but we can attack the caterpillars, more especially those of the large white than those of the small white, because the latter get inside the hearts of the plants and continue their destructive work well out of sight. I recommend light applications of dust-dry lime followed by very heavy syringings of cold water. The caterpillars thrive in warm, dry weather and are easily killed by cold and wet. Katakilla powder is also very effective as a preventive and remedy.

Slugs and Shell Snails.

The field or milky slug, measuring, extended, about 1½ins. long; the black slug, much longer; and the shell-snails are the gardener's aversion on account of their great numbers and large amount of damage they are capable of doing. Where the haunts of the shell-snails are, there you will find thousands of young ones in due course—in empty pots, hollows in banks near to a large stone, in dry walls and similar places. Unless you turn up some object under which a shell-snail is clinging to something, you will rarely find them abroad during the daytime. So it is a good plan to hunt for them on grass, near any decaying leaves or close to the beds of lettuces and cabbages soon after sunset. They may be found in hedges of the common laurel and shaken down, gathered and destroyed. I have myself found the plan of looking for and killing them the best way, and followed it up till as late as midnight. The milky and black slugs have the power to slough off any applications of lime, soot or salt for several times, and do so successfully if the applications are weekly, or even bi-weekly ones, as the pests have time to fill up their store of slime. But if the applications are daily ones and put down where the slugs come out to feed, the latter will be conquered, because the substance falls on their unprotected skin and kills them. The same principle applies to other kinds of remedies mainly, such as "Slugene."

The Celery and the Parsnip Fly.

The fly is very busy in spring and again in July. No doubt many readers of THE GARDEN are now troubled about the maggot-infested leaves. It is too late to do anything more than the removal of bad leaves and the crushing of the maggots in slightly affected ones. But the cultivator who is anxious to get rid of the pests next year should begin operations now or soon. When the crops have been used simply level the soil on the space and on a few feet all round if possible. Spread hedge trimmings, dried grass or weeds or anything similar, even a few shavings, to the depth of 6ins. at least, and sprinkle paraffin on it. Set this alight and even feed the fire a little if there is ample material, or, better still, turn over the top 4ins. and burn more rubbish on it. In this way you will destroy the maggots as



Garden white butterflies: The small white (Pieris rapæ), the large white (P. brassicæ), female and male.

they enter the top crust of soil to go down and turn into pupæ, from which they emerge next spring to trouble you again. No doubt a good dressing of vaporite and other soil fumigants would do a lot of good where burning cannot be carried out.

The Codlin Moth.

It is now time to band apple and pear trees, also all supporting stakes. Instead of being content with one band, apply two—the lowest 1ft. from ground-level and the second 6ins. above it. The bands should be well greased and applied on a part where the bark has been judiciously smoothed to allow of the close fitting of the greased band. Use wire to fasten on the bands, then they will not tighten nor slacken according to weather changes.

CHRISTCHURCH.

CLEANING THE GARDEN

WITH the fall comes an excellent opportunity for a general cleaning of the garden. This is really one of the best opportunities that arise for tackling the weed problem. If the weather is fairly damp and mild, as is usually the case, the seeds of large numbers of the common weeds, both annual and perennial, start growth. Destroy the young plants now and you will take a long step towards a weed-free garden next year. Even in the best-kept garden it is likely that the clearing of beds and vegetable patches will disclose some of the strong-growing perennial weeds like docks, dandelions, etc. These should

A clump of Michaelmas daisies to be divided for replanting.

The wrong way to plant. Each portion is too large and planted too closely together.

The right way. The portions are small in size and have ample room to grow.

Digitized by Google

be bodily uprooted, as even small pieces left in the ground are quite likely to grow. If by any chance these plants have got as far as the production of seed, take special precautions. Do not walk over the garden waving a large thistle plant and so allow the downy fruits to spread in all directions. If you do you will be laying up much trouble for next year. Neither should weeds of any kind ever be stacked up on a rubbish heap and left there to rot. Most of our common weeds have an amazing amount of vitality, and they are quite capable of bursting into flower, setting and ripening seed, even if they are not actually in the soil at all. By far the safest way is to burn weeds of every description at the earliest possible moment and so, once and for all, put an end to their harmful careers. It is worth while making up a special fire of some dry litter, and when this is burning strongly to spread the green weeds in thin layers on the glowing embers.

In addition, the autumn is a great time for the suppressing of insect and other pests. At this season, when roots are being lifted and digging generally is the order of the day, there is much disturbance of the soil. Keep a sharp look-out for grubs of all kinds. When digging potatoes it is worth while giving the soil a little extra turn in order to bring to light such things as wireworms, leather jackets, etc. All should be collected and destroyed without mercy. When ground is vacant an excellent plan to adopt is on the following lines: Make a very hot solution of soft soap and water (about an ounce of the soap to every gallon of water) and sprinkle the ground in sections with this before it gets absolutely cold. Large numbers of grubs of all kinds will pop up, and these should be seized before they have a chance to escape. At the approach of the winter earwigs, woodlice, snails, slugs and a host of other pests betake themselves to cracks in fences and any positions where protection can be secured. It is worth while examining situations of this nature and thus reduce the number of noxious things in the garden generally.

Clearing up the Herbaceous Border.

At this season of the year a certain amount of time must be devoted to setting things straight in the herbaceous border. One should not approach the problem in the spirit of the average jobbing gardener, who would cut everything down in order to make things tidy for the winter. As a matter of fact, it is wiser to let the plants complete their natural growth before bringing the knife into operation. It cannot be too often insisted that plants exist by means of the food material which they elaborate, with the help of light, in their leaves. Thus, to remove masses of healthy green foliage is to take away nutriment which should properly be stored away in the roots. In the case of a very strong-growing plant this might do no more than give a slight check to its vigour; with a less robust specimen the effect would be an inferior production of blossom next season. Of course, any plants that are obviously dying away may have their stems cut to within an inch or so of the ground. Incidentally, it may be mentioned that the dried stems of asters and many other herbaceous plants if stripped of their leaves, and cut into convenient lengths, make excellent spills for pipe lighting, etc.

Usually it is impossible to make a clean sweep of the herbaceous border at one time. Some varieties of aster, for instance, naturally flower late. In addition, many perennials when well established are apt to start away a second growing season if the fall is genial. There is every reason for allowing this to proceed, for quite often a bright display of flowers is the result, and no possible harm is done to the rootstock. Take note at this time of any plants which seem to be in the wrong place, and correct the errors by removal when the clumps are at rest. Again, mark down any subjects that tend to take up more room than is their share, and plan to reduce these or, perhaps, take them away altogether. Replace any labels that are difficult to read or have become lost. It is an excellent plan to make a practice of labelling subjects in the herbaceous border. Then, when making any alterations or additions, it is easy to know just what you will get in the way of colour effects.

After cutting down any clumps fork the soil lightly and clean the ground of any weeds. The heavy rains of autumn will, at times, tend to lay bare the tops of the roots, and this is a very unnatural state of affairs. In a wild state these perennial plants would be covered with dead leaves and decaying vegetation, and it is worth while making some attempt to reproduce this condition. It is a very excellent rule in the case of all herbaceous subjects to scatter lightly a layer of good soil over the roots after the stems have been cut down. This may be repeated once again in the very late fall, and it will be found to have a highly beneficial effect on the herbaceous subjects of all kinds.

AN EXAMPLE OF A BORDER WHICH REQUIRES THINNING AND CLEANING DURING THE NEXT FEW WEEKS.

Lifting Tender Plants.

Towards the latter part of September the weather usually shows signs of breaking up. Geraniums, marguerites, heliotropes, begonias and a host of other subjects that make the garden bright during the warm days of summer are evidently feeling the effects of the chill nights of autumn. Even if it is not really cold steps should be taken to lift all tender plants that cannot face the winter in the open border. Choose the dryest possible day for the business, and have pots and soil at hand before actually digging anything up. Lift with as little root disturbance as possible and get the plants quickly settled into the pots. Often this work is done carelessly, and this is a pity, for many of these specimens, if properly treated, will flower freely during the winter in a cool greenhouse or conservatory. Of course, begonias, gladioli, etc., will have to be dried off, after lifting, in some warm, dry place, the tubers or corms being finally stored in dry sand. Take care in the case of every subject to attach a label giving the name of the variety or, at least, the colour of the flowers. In these times of removal it is very easy to get the plants mixed up, and it is most annoying to find that one does not know in the least what any particular specimen happens to be.

Plants in pots should be kept in a cool place, and it is best not to place them under glass at once. Providing there is no serious risk of frost they are better left out of doors for a week or so at any rate. Probably little watering will be needed, but care should be taken to remove all dead flowers and foliage. Where it is wished to use plants as stock for the taking of cuttings in the spring a drastic cutting back of geraniums, etc., is advisable. On no account should this be done until it is certain that the specimens have settled down into their new quarters. It is a fact that geraniums will survive the winter when suspended by their roots in a cellar, but it is much better to treat them in a more natural way. Let the winter quarters of these tender plants be light and airy. Providing there is no risk of frost a great degree of heat is not desirable, and a few specimens may easily be wintered in the sunny window of a living room. Until active growth starts again it is wise to keep the soil on the dry side, and, whenever the weather is mild, air from the outside should be freely admitted.

When lifting the tender plants it is worth while selecting a few of the best for placing in a conservatory or room. Choose those which are sturdy and have plenty of developing flower-buds on them. After a few days, when the plants show signs of recovering from the shock of removal, place in the conservatory or a sunny window and a wonderful show of bloom will be the result. The writer has kept a small conservatory gay with lifted bedding plants right up to Christmas, and even into the early months of the New Year.

OUR SERVICE BUREAU

Though so many subjects are dealt with in each issue of THE GARDEN, *it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, there is always information available from a staff of expert contributors and consultants; and there is no charge for this. It is one of the additional means of service which* THE GARDEN *is glad to render to its readers.*

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope and the coupon, that will always be found in each issue, shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2.*

We have selected the following enquiries, with their answers, as being of more general interest, and therefore worthy of publication.

Edging Plants for Borders.

I have a border 200yds. long, and I should be glad of your advice about edging plants.

I notice you mention in your paper, in an article on Edging Plants, such flowers as pink and white thrift, Mrs. Sinkins pinks, Senecio argenteus, Campanulas pusilla and G. F. Wilson, aubrietias. Achilleas, too, are mentioned, and Colchicum speciosum. Can these all be used together? How many of each should I want for a border a yard wide and length as above? What month should they be planted?—G. H.

We suggest that you plant the edging plants which you mention at intervals along the border, blocks of pink and white thrift mixed with Pink Mrs. Sinkins, Campanula pusilla, aubrietias and achilleas. Colchicum speciosum we should be inclined to omit. The plants should be placed fairly close together, and you will require, roughly speaking, about fifty plants of each—probably more. You will be able to judge better after you have planted a number of them to see how the border is planning out. All these can be planted during the next few weeks, say some time in October; or planting may be withheld until the early spring. On the whole, it is better, however, to plant in the autumn this year, as the plants will then have a chance to become established, and will probably flower better next spring and summer.

Transporting Millipedes.

The garden of this town house is infested with millipedes, though I have endeavoured to reduce the number by potato traps, etc. I am hoping shortly to be removing to a house in the country, and would like to take with me a few specimens from this garden. Can you tell me of any course I can adopt so that I can be reasonably certain I shall not take the millipedes with me? There should be little risk, but they are so numerous that they appear to have abandoned their carnivorous habits and cling to the roots freely. Bulbs, violas, wallflowers, carnations, lupins, all seem to have the young millipedes at the roots, just as carrots suffering from fly. Water does not appear to drown them. Salt water would, presumably, kill the plants. The soil here is very sour, though I have dressed it with chalk and lime. The land I am going to is meadow land, where I shall probably find quite enough enemies without adding any.

I should be very grateful if you could tell me of some means whereby I could ensure there were no young millipedes, even the tiniest, and no eggs left in the crannies of the roots. I should indeed despair if the plague were to be established in the new garden.—E. D. S.

We do not wish to dishearten you, but we do not think it very likely that you will be able to remove soil from your garden without also taking some of the millipedes. However, you can try to prevent such happening by watering the soil around the plants with nitrate of soda solution a day or so before removing them. Use 1 oz. to 2 gallons of water, or a strong solution of common salt 1 oz. dissolved in 1 gallon of water. Several days before lifting your choicest plants procure some farmers' cotton cake, break it up and scatter on the soil surface round the plants. Millipedes like it, so you may in this way catch and destroy them.

A Remedy for Slugs.

What, in your opinion, is the most effective remedy for slugs? I understand that Leeds University have a mixture of kainit and, I believe, copper nitrate, which, although harmless to plant life, spells instant death to the slug. Do you know of this?—T. B.

A good remedy for slugs is one part of copper sulphate and 20 parts of kainit, mixed together and applied at the rate of 1½ oz. per square yard. This ought to be done while it is dark.

Cutting Back Rock and Herbaceous Plants.

Some of the rock plants in my garden are beginning to look straggly, such as the aubrietias, saxifrages, etc., and, as my rock garden is on the small side, I want to cut these back. The question arises as to how far or close one should cut them. I have other carpeting plants which are thus being covered.

When a herbaceous border containing lupins, delphiniums, aquilegias has finished flowering, I am told that they can be cut down to ensure tidiness. Once again, how close are these to be cut?—T. W.

For such spreaders as aubrietias and saxifrages, they are unharmed by thorough cutting back. Probably the best time to do it is about September or the beginning of October, and really it makes very little difference how much you use the knife.

The herbaceous border can certainly be cut to the ground, but only after the flowering season is completely over. This, of course, depends on the weather, but will certainly not be before the first half of October; then it can be cut right to the ground.

A Preventive for Rhododendron Fly.

I enclose a few leaves of Rhododendron fastuosum which seem to be diseased. The plants affected have produced very little young growth. They have been in about four years and have done very well till this summer. Other groups of rhododendrons in the same border look quite healthy as usual. The plants look as if they had got red spider, but I do not actually see any red spider on the leaves.—D. P.

The rhododendron leaves are infected with the rhododendron fly, and I may say that we have never seen a worse case. Luckily the fly is a slow spreader. In mild cases the method of cure is to spray the plant thoroughly with an emulsion of soft soap and water. However, it appears that in this case the plants are too bad, and I should strongly advise you to dig them up and burn them now to prevent the pest from spreading to other plants.

Mealy Bug on Vines.

The vines here are literally covered with mealy bug, some of the bunches of grapes being already spoilt. I have been using methylated spirit on get-at-able places, but, of course, I cannot get into the bunches. I wonder whether fumigating with XL-All would be of any benefit and whether the fumes would deposit any poison on the berries so as to make them injurious to the consumers.

The berries have not commenced to colour yet and will not do so for some time. Is there anything else that could be used now?—A. W.

There are several fumigating compounds available, but it is considered risky to use them after the stage when the grapes begin to soften for ripening. Always ask the manufacturers' advice in such cases. To meet your present case, we advise you to wait until the grapes are ripe, and then syringe out the mealy bug from each bunch, as it is used, with clear water, suspending it in an airy place to dry. When the vines are pruned and cleaned, use Gishurst Compound on the vine rods, lime wash on the walls, soft soap and paraffin on the wood, and pure paraffin on all wires and other ironwork.

Training Yew Trees.

Last spring I planted a yew hedge of quite small trees, about 1½ft.–2ft. high and 18ins. apart. I want it eventually to be a clipped hedge dividing kitchen from flower garden. How soon ought I to begin to clip it, and at what time of year?

I suppose, in any case, I must not clip the top shoots, which will carry the hedge up?

Some four or five years ago I put in two small yews at either end of a stone seat: they are now about 5ft. high and have been allowed to grow naturally. I should like to clip them, so as in time to have them rounded pyramids (or cones). At what time of year should I clip them, and how much should I clip them? Is it best to begin by just shortening the ends of the longer branches, and then, another year, cutting them more into shape, or should I begin by cutting them back into the required shape, and leave the trees to "fill out" and gradually get an evenly rounded surface? Here, also, must I leave the top leading shoot?—H. M. L.

We should suggest that you leave the newly planted yew hedge for a year or two before touching it with the knife. It must be allowed to grow naturally and form itself into a bushy habit. In order to keep it in shape, clipping can be carried out during the early summer, preferably on showery days, but too much should not be taken off the plants while they are young. Later on, when the hedge reaches an average height, it can be "topped," so as to produce bushy growth at the base, and give you an even, bushy hedge from the bottom upwards.

The clipping of the two small yews which you mention should be carried out in early summer or early autumn. Again, the actual work is best carried out in showery weather. Do not cut off too much at once. It is probably best to begin by shortening the ends of the longer branches, which will prompt more bushy growth. After this is done, an attempt can be made at shaping the plant. If this method of doing the work by degrees is followed, the trees do not lose in appearance, as they have time to recover from the first shock of clipping. In this case, if you desire a pyramid or cone shape, it will be necessary to clip the tree to the leading shoot, leaving it untouched if you still wish the plant to gain in height.

Small Orchards

No matter how small or large the orchard, it pays to use Stictite Tree Banding Compound.

Winter Moth rises from the soil early in October or late September, and the females (being wingless), at once crawl up the tree trunks in order to deposit their eggs in the branches.

By banding the trees with Stictite in the autumn you can prevent the eggs being laid, and so avoid having to spray for the caterpillars in the spring.

1 lb. of Stictite will do 9 to 12 trees of about 8 in. diameter.

½-lb. 1/6 (post 6d.); 1-lb. 2/9 (post 6d.); 2-lb. 5/- (post 9d.); 4-lb. 10/- (post 9d.); 7-lb. 17/6 (post 1/-).

Greaseproof Paper, 5 ins. wide: 6 yds., 2d.; 12 yds., 3d.; 25 yds., 6d.; 50 yds., 9d.; 100 yds., 1/6; 200 yds., 2/6.

Write for Descriptive Folder.

Stictite is sold by Nurserymen, Seedsmen, Florists, Ironmongers, Chemists & Stores. If any difficulty, please write to Abol Limited, 9, Beltring, Paddock Wood, Kent.

NEW AND RARE PLANTS AT HOLLAND PARK

ORCHIDS.

Messrs. Cowan and Co. staged a representative group of autumn-flowering orchids. The back portion was composed of Dendrobium Phalænopsis intermixed with well flowered plants of Odontoglossum grande, while the main area was filled with Cattleya Vesta, pure white; C. Helidor, apricot yellow; C. Harold alba; and Lælio-Cattleya luminosa aurea. Cypripedium Bedfordiæ, with an unusually large flower, but somewhat deficient in colour, was arranged with C. Ernest Read and C. Royal George.

Messrs. Black and Flory, Slough, had an effective group of Cattleya hybrids, mostly obtained through C. Warscewiczii var. F. M. Beyrodt, in which the white sepals and petals are a well known character. Novelties were staged in Cattleya Marlow and Lælio-Cattleya Colnbrook.

Messrs. Stuart Low and Co. had a group at the end of the hall. It contained the rare Æranthus grandiflorus from Madagascar, Eria bicolor, the scarce Paphinia cristata, an attractive example of Vanda coerulea, also Cymbidium erythrostylum and the charming Sophronitis grandiflora.

Messrs. Charlesworth and Co. staged Odontioda Pamela var. autumnalis, a showy hybrid with large flowers strongly indicating the O. Harryanum parentage, the lip usually large, bright purple, with a white apical half.

Orchid Committee Awards of Merit.

LÆLIO-CATTLEYA PROFUSION, STAMPERLAND VAR. (L.-C. Serbia x C. Hardyana).—A very showy hybrid possessing a robust constitution. The present example bore a spike of four large flowers with the segments well displayed, the petals broadly developed and of soft rosy mauve colour, the labellum intense purple on the disc and marginal zone, and with a yellowish area on each of the lateral lobes. Shown by Mr. Robert Paterson, Glasgow.

LÆLIO-CATTLEYA GENERAL MAUDE VAR. SPLENDENS.—This handsome hybrid bore a couple of widely developed flowers of rich mauve-purple evenly suffused throughout the sepals and petals, the roundly formed labellum purple-crimson with some golden venation in the throat portion; one of the best varieties of this hybrid between L.-C. Rubens and C. Hardyana. Shown by Messrs. Cowan and Co.

CATTLEYA LORNA VAR. EMPRESS.—In this hybrid between C. Warscewiczii var. F. M. Beyrodt and C. Enid alba the white sepals and petals of both parents are inherited. The bright purple colour of the disc of the labellum is a pleasing contrast, while the clear yellow in the throat portion is another feature. Shown by Messrs. Black and Flory.

CATTLEYA MIMOSA VAR. GOLDEN QUEEN.—A very beautiful hybrid obtained by crossing C. Venus with C. triumphans, both of which are noted for their attractive yellow colour. The segments are of thick texture, the petals broad and up-standing, with undulated margin and of clear yellow colour, the labellum pandurate in form and of rich ruby colour. Shown by Messrs. Cowan and Co.

BRASSO-LÆLIO-CATTLEYA MATTHES.—A particularly pleasing hybrid obtained by crossing the yellow-flowering B.-L.-C. The Baroness with the white-flowering C. Maggie Raphael alba. The segments are effectively arranged and of a clear yellow colour of unusual brightness, the labellum alone showing some slight cerise markings. Shown by Messrs. Stuart Low and Co.

Floral Committee Awards.

AMARCRINUM HOWARDII.—This plant is of special interest in that it is one of the very rare instances of successfully crossing the Amaryllis Belladonna with another bulbous plant. A few years ago Dr. Attilio Ragionieri, using a crinum, apparently C. Moorei, as the seed parent, successfully fertilised it with the pollen of the belladonna lily and named his bi-generic hybrid Crinodonna Memoria Corsii. But the plant shown at the R.H.S. Autumn Show represents a more valuable instance of the reverse cross. At Los Angeles Mr. F. Howard succeeded in crossing Amaryllis Belladonna with pollen from Crinum Moorei. He sent a few of the seedling plants to Mr. T. Hay of Hyde Park, who gave two to the Royal Botanic Gardens, Kew, where the stronger flowered last year in a warm border out of doors. The flower-spike grew to about 4ft. in height, but Mr. Hay's plant, which received the award, being in a flower-pot, is not so tall. It has nine flowers altogether, and these have the tips curved outwards as in the belladonna lily, while the spike itself is much like that of a crinum. The flowers are of a lovely soft shade of pink. The bulb is necked as in crinums, but the leaves are narrow like those of Amaryllis Belladonna. First-class certificate. Shown by Mr. T. Hay.

APHELANDRA TETRAGONA.—This tropical bromeliad requires hot-house culture. The opposite, pale green, ovate-lanceolate leaves are about 7ins. long, and the terminal four-square inflorescence is composed of brilliant orange-scarlet flowers. Award of merit. Shown by Messrs. L. R. Russell, Limited.

CLERODENDRON FŒTIDUM.—A vigorous evergreen shrub from Nepal, and is only suitable for outdoor cultivation on warm borders in the southern counties. The foliage is handsome and the large, compact heads of rose-coloured flowers are produced at the ends of purplish growths. The flower-buds are of a rich vinous crimson colour. Award of merit. Shown by Mr. G. W. S. Loder.

BERBERIS THUNBERGII ATROPURPUREUM.—A neat, compact little specimen bearing leaves which, when young, are a beautiful clear rosy colour. The older leaves are reddish purple. Award of merit. Shown by Mr. Amos Perry.

SALVIA "BLUEBEARD."—We have given the name by which this salvia is said to be known in Chili; its correct name has to be determined. It is an erect herbaceous plant bearing stout, opposite, shining, ovate leaves, which are regularly toothed and are paler on the undersurface. The terminal spikes have foliaceous whorls of up to four dark blue flowers about 2ins. long. It was hardy throughout last winter. Award of merit. Shown by Mrs. Philip Martineau.

BIARUM EXIMIUM.—An attractive little aroid from Anatole. The velvety purple spathe, which is spotted below, is produced from the dry and leafless corm. Botanical certificate. Shown by Mr. Amos Perry.

ASTER RUBY TIPS.—The ruby colour was not apparent in the uncertain light of the hall, where the medium-sized round flowers of this Michaelmas daisy appeared to be of a pleasant pink colour. Award of merit. Shown by Mr. E. Ballard.

SCOLOPENDRIUM VULGARE SAGITTATUM CRISPUM.—This is a very good, compact form of the hart's-tongue fern, with regularly waved and undulated dark green fronds. Award of merit. Shown by Mr. Amos Perry.

SOLIDAGO × BALLARDII.—A tall-growing golden rod bearing narrow, erect spikes of yellow flowers. Award of merit. Shown by Mr. E. Ballard.

CHRYSANTHEMUMS JANET WYBER, MADELINE AND PEERLESS, which received the first-class certificate of the National Chrysanthemum Society, were also given the R.H.S. award of merit.

HOW TO GET THE BEST OUT OF YOUR CHRYSANTHEMUMS

Treatment of Exhibition Blooms.

UNDOUBTEDLY, amateurs like to excel in the culture of chrysanthemums for big blooms, and the latter will soon be ready for the show table. It is, now, the most interesting stage of the plant's growth, as the blooms are developing rapidly and require constant attention. If they are well managed only a small percentage of blooms will be lost. On the day of the show the blooms and the specimen plants must be at their best, fully developed, but quite fresh. To obtain such flowers, certain varieties will need some shading in sunny weather; others, which are backward, will require full exposure and, perhaps, a little artificial heat, but we should always bear in mind the fact that the blooms are best when they are developed slowly in a rather cool temperature. After a bloom is half open it fully expands in a short time, approximately sixteen days, so that the grower should not be over anxious in this matter and spoil good flowers by subjecting them to a high temperature and close atmosphere.

SHADING.—Early in the morning, before the sun shines on the house in which the plants are, put on a light, temporary shade if the night air has been very damp and foggy. The mischief of damping is done, mainly, by the sun shining on the damp petals; the light shade and judicious ventilation will combine to ward off the evil of damping.

WATERING.—The watering of the plants should next be attended to; if the soil is rather dry apply clear water only. Manure water may be used early in the day to soil of sufficient moisture. Again at midday examine the plants in case some need water. After midday do not water any plants; wait until the next morning. If a plant, bearing blooms developing well, has a very dry soil, apply water at once, and only clear water for nearly a week afterwards. It is a mistake to keep the soil in pots very dry with a view to avoiding the damping of the blooms, as such excessive dryness of soil conduces to the damping.

VENTILATION AND PESTS.—Air allowance should be increased gradually early in the morning, and as gradually reduced after two o'clock in the afternoon. If fire heat is necessary, it should be applied so that the pipes will be warm by sunset so that there will not be any sudden lodgment of moisture on the blooms. Also the day should begin and end with a thorough search for earwigs. Every week fumigate the house with Darlington's Auto-shreds or any other approved fumigating material to keep down aphides, as if once they get established in the blooms it is a most difficult matter to kill all.

FORWARDING AND RETARDING THE BLOOMS.—As varieties vary much as to the time of flowering, it will be necessary to watch the opening blooms closely. The backward plants should be placed in good time in the

warmest part of the house and the more forward ones in the coolest. Always avoid a very close atmosphere as it does not help the blooms forward, but spoils them. Nitrate of soda or sulphate of ammonia may be used to hasten development, but I do not advise its use, as the blooms open with flimsy-textured petals, which soon fade.

Bush-grown Plants.

These should be placed in the vinery, peach house or greenhouse directly the flower buds can be clearly seen. At this stage any necessary disbudding should be done. Open the ventilators wide during the first fortnight or so, then restrict ventilation somewhat, but always allow ample fresh air to enter. At every watering weak doses of manure water may be given.

The plants forming the latest batch, to supply flowers about Christmas, may be kept outside in a sheltered place until nearly the end of October. If the position is such that it will allow of a temporary shelter being fixed in case of frost, the tender shoots and buds will not be damaged. Feed these plants lightly. GEORGE GARNER.

TIMELY REMINDERS

Cuttings of Currants.

OCTOBER is a very good month for the taking of cuttings of red and white currants. Select young shoots about a foot long and cut just below a bud. Remove the buds down the stem with the exception of three or four at the top. Insert the cuttings about 6ins. deep in rows, pressing the soil firmly round them. With red and white currants the idea is to get a bush with a clear stem above the ground. In the case of black currants a similar plan is adopted, except that no buds are removed. Here the object is not to secure a bush with a clear stem, but to get as many young growths from the base as possible.

The Lawn in October.

ABOUT the first week in October the lawn should have its final mowing and the edges trimmed with shears. It is a mistake to continue cutting grass right through October, as is sometimes done. When treated in this way the lawn has not the same opportunity of thickening to withstand frosts. As a result, the spring growth is not so robust as where the grass has carried a longish growth during the late fall and winter.

Keep an Eye on the Parsnips.

PARSNIPS should be left in the ground until required for use as, if removed from the moist earth, the roots soon shrivel. As well, too, this excellent vegetable is always in better flavour if it has been exposed to a certain amount of frost. It is a mistake to neglect the parsnip bed completely at this season. Weeds grow apace during the mild wet weather which we are likely to experience, and these should be steadily kept down. Then an occasional stirring of the surface soil will go a long way towards helping the parsnips to complete their final stages of growth.

Winter Mint.

FRESH mint is always very acceptable in the winter, and it is not difficult to secure. When the foliage of the plants dies down during October, lift a certain number of the roots. Leave these exposed on the surface of the soil for two or three days and nights. If there is a slight frost this will do no harm, but be, rather, beneficial. Then plant the roots in pots or boxes of soil and, after about a week, place where there is a mild heat. A position under the staging of a greenhouse, or in a nearly worn-out hot-bed is admirable. After an interval the roots start to send up new shoots, and useful gatherings of winter mint may be made as required.

Fruit Tree Planting.

THERE is no doubt that early planting is highly desirable with all fruit trees. If the trees are set while the ground is still warm, they have full opportunity of taking a firm hold before the winter sets in, and the chances of failure are much reduced. There seems a widespread idea that fruit trees to be a success need vast quantities of manure, but this is not the case at all. Almost any ordinary garden soil of good quality will suit them very well indeed. In taking out the holes be sure and make these big enough to accommodate the roots without crowding. In addition, dig the soil to a depth of 2ft. so that the commencement of a free root action is easy. If you strike a stiff clay subsoil, it is usually better to take this right out, remove it to another part of the garden, and fill the place with fresh surface soil. Leave a little mound in the centre of the hole on which to rest the base of the tree and spread out the roots. Tread the soil in well as it is placed over the roots.

About the Herbaceous Border.

AS the season draws to an end some attention must be given to the herbaceous border. Of course, the majority of the perennial plants commonly grown which die down in the winter are perfectly hardy, but this is not so in all cases. Except in some of the mildest localities, dahlias cannot safely be left for long after the first frost has blackened the foliage. When this happens, the best plan is to cut the tops to within 6ins. of the ground and, on a dry day about a week later, lift the roots carefully with a fork and place them in some airy outhouse. Attach the names of the plants to the stems so that one may know just what each happens to be. Leave the roots until all moisture has gone out of the stems and then put in some cool, and preferably dark, place where there is no risk of frost. If the roots are to keep well, dryness is essential over the resting period. While a certain number of the early-flowering gladioli are hardy when once established, these plants, as a whole are best lifted in the autumn. The right time to do this is when the leaves become yellow. After lifting dry the corms out of the sun in an airy place and then put in paper bags which are kept in a cool frost-free place. Take care to mark the names of the varieties on the bags or, if these are unknown, give some indication of the colour of the flower to avoid confusion when planting time comes round. The young offshoots, from which fresh plants are easily raised, should not be removed from the corms until the spring. Another herbaceous perennial which is not able to face the winter is the canna. As soon as the weather becomes definitely cooler cannas show signs of flagging, and then is the time to lift the roots. Remove carefully from the ground with as much soil attached as possible. Then store in boxes filled with dry earth and keep in an absolutely frost-free place. Cannas are easily propagated by root division, but this should not be attempted until the spring. Here, again, some form of labelling should be adopted so that next season it will be possible to know the different varieties.

MANURING & LIMING SOILS

THIS is a matter that affects everyone who grows fruits, flowers, vegetables and trees of all kinds. Crops deteriorate if the soil is not enriched with manure in organic or liquid form. In the former condition the beneficial effects are more lasting than in the latter. Applied in a liquid form the stimulants' power is soon exhausted because it is easily washed down below the point where the roots of the plants grow, or is evaporated into the air. In organic form the exact position of the bulk of the manure can be determined when it is applied. From time to time the nutriment it contains is liberated for the benefit of the plants, the roots of which often thoroughly permeate the manure and absorb strength from day to day. The concentrated manures act more quickly than farmyard and similar manures and should always be applied with great care, then they are immediately beneficial. They are not, as a rule, applied to plants with few roots, but to those possessing many roots which have absorbed the nutriment contained in the soil and need continued sustenance; then the concentrated manures act as stimulants, as manures in any other form will not—especially in the limited time left to the plant before its maturity.

Lime.

Lime is very essential if the best is to be obtained from the soil we till. Many people do not regard lime as a manure, but to some extent it is, as it contains salts that are most beneficial to practically every vegetable we grow. To be absolutely sure as to the benefit certain plants will derive from an application of lime it is necessary to have a true analysis of both the lime and the soil, as both vary so much in the different districts and even in various parts of the same district. These are essential details that cannot, beneficially, be dealt with in this article. Some limes contain much magnesia, which absorb carbonic acid slowly and remains in a caustic state, then the roots of the plants are injured, as it reduces the benefit from the carbonic acid evolved by the decomposing parts of the soil. Even in our elementary knowledge we refrain from applying lime to rhododendrons, azaleas, bog and heath plants generally because on the surface of it all we see such plants die or just exist when they have come into contact with lime incorporated in the soil. Bog soil contains gallic acids, and if lime is mixed with such soil those acids are lost. Now we will return to the question of

Manuring.

Manures may be vegetable, mineral or animal. In recent years the latter was the one with which gardeners were most concerned. Now, perhaps, there is a more even balance between the three forms. As the season of digging is coming, our thoughts are of the various forms of manure which we ought to use and, I daresay, organic manures occupy our thoughts most. If we had our choice we should apply cow and pig manures to light and horse manure to heavy soils. For the benefit of autumn crops—crops put in during the early autumn time—we would prefer rotted to fresh manures, but where there is not any choice and fresh manure must be used, then it is a wise plan to dig it in a little deeper than usual so that the tender roots of plants will not come into direct contact with it too soon. Generally, fresh manures should be dug into soils during the autumn and the surface portion left in a rough, lumpy state where the crops are to be put in during the spring. For all root crops, where the soil unmanured is too poor for them, autumn manuring is always the best.

In the case of sandy or very light soils, organic manures are best applied in the spring, because owing to the great porosity of the soil the major part of the goodness they may contain would be washed down by the winter rains quite out of the reach of the roots of plants occupying that particular plot of ground from spring onwards.

The way in which manure is applied to the ground is important. It should not be put on the ground and just got rid of by burying it anyhow. By far the best way is to place the manure in heaps conveniently so that it will not be unduly dried or washed by sudden rains. Then the workman as he turns over the soil should spread the manure in the trench made, mixing it evenly with the soil from a few inches below the surface to a foot or even more for certain root crops. This way is much better than spreading the manure on the surface and digging it in thinly in some parts, thickly in others. Furthermore, it adheres to the boots and is unpleasant. Do not bury it in largel lumps but in small ones.

Lime has the beneficial effect on hard, clayey ground of breaking up the lumps and so making the whole more easily worked as well as more productive. It is a great sweetener and purifier of the soils we have to deal with and in certain cases, where the soil has been overmanured and become sour, an application of lime will in a year's time rectify matters. Lime kills insects and guards plants to a considerable extent against club-root. Fresh slacked lime is the best to apply, and in a powdered condition, not in large lumps. The autumn is the ideal time of the year for its application and about 6 oz. per square yard a medium-strength application.

G. G.

CATALOGUES RECEIVED.

Messrs. Chaplin Bros., Limited, Paul's Royal Nurseries, Waltham Cross.—A catalogue dealing chiefly with roses. Hardy conifers, evergreen and deciduous shrubs and herbaceous plants are also given. A bulb list has also come to hand.

Messrs. W. Drummond and Son, Limited, 57, Dawson Street, Dublin.—A bulb and autumn planting catalogue. A useful selected list of insecticides and horticultural manures is included.

Messrs. E. P. Dixon and Sons, Paragon Square, Hull.—Bulbs for early forcing, hyacinths for pots, daffodils for the woodland and bulbous plants for the rockery are given in this firm's catalogue.

The Orpington Nurseries, Limited, Kent.—A catalogue of irises of all types. Careful colour descriptions of some of the novelties introduced during 1926 are given.

Messrs. W. Bignell and Son, 48, North Road, Highgate.—A list of bulbs for cultivation in bowls and in the garden.

Messrs. McHattie and Co., Chester.—Bulbs, roses, shrubs, fruit trees and perennials for the herbaceous border are listed in this firm's autumn catalogue of nursery stock. All the roses are British grown.

Messrs. A. Ireland and Hitchcock, Marks Tey, Essex.—In many districts autumn-sown sweet peas give the best results, and those contemplating seed-sowing within the next few weeks should write for this firm's list of new and old varieties of home-grown sweet peas.

Mr. A. Dawkins, 408, King's Road, Chelsea, London, S.W.10.—May-flowering and Darwin tulips for massing in beds and borders are a special feature in this catalogue.

Messrs. D. Prior and Son, Colchester.—These rose specialists have sent us their new rose catalogue, including novelties for 1926 and the best of the old varieties.

Messrs. Dickson, Brown and Tait. 57, Cross Street, Manchester.—Attractively produced catalogues of bulbs and roses, illustrated with numerous coloured plates, have been received from this firm.

Messrs. John Waterer, Sons and Crisp, Twyford, Berks.—A carefully compiled catalogue of hardy perennials and alpine plants. The height, colour and blooming season of each plant is given, and, in many cases, notes on the most suitable site are also included. The numerous excellent half-tone illustrations of various plants growing in the garden should be found most useful, as they give a fair idea of the habit and the situation in which the plants are likely to flourish.

Mr. W. J. Unwin, Histon, Cambs.—A sweet pea, bulb and gladioli list. A number of 1926 sweet pea novelties are included.

Primley Botanic Nursery, Paignton, South Devon.—A list of hardy and tender shrubs, both deciduous and evergreen. The season of blooming and the origin of each shrub are given. This catalogue is interesting from the botanical point of view.

Mr. H. Hanchet, Crab Hill Lane, South Nutfield, Surrey.—A selection of British-grown roses, fruit and climbers.

Messrs. W. Cutbush and Son, Barnet, Herts.—A special list of strawberries and roses for bedding, pergolas and hedges.

Mr. Thomas Carlile.—A general catalogue of hardy perennials. Particularly good selections of delphiniums, lupins and irises are given.

Messrs. Pennell and Sons, Lincoln.—Copiously illustrated is the bulb catalogue sent in by this firm. Plants specially prepared for forcing, such as azaleas, deutzias, hydrangeas, lilacs, spiræas, are also included.

Messrs. Cooper, Taber and Co., 90, Southwark Street, London, S.E.—A wholesale bulb catalogue which should be of interest to anyone wishing to buy bulbs in large quantities.

Mr. Amos Perry, Enfield.—A special early offer of bulbs and tubers, new June-flowering irises, for early autumn planting. A number of uncommon and rare bulbs are listed.

FOREIGN.

Messrs. John B. Vanderschoot, Hillegom, Holland.—An illustrated catalogue of selected Dutch bulbs has been received from this well known firm of bulb growers.

Messrs. J. B. Wijs and Son, Amsterdam, Holland.—Tulips, narcissi, hyacinths, crocuses and miscellaneous bulbs are given in this list.

TRADE NOTE.

OWING to the continued expansion of their Landscape and Rock Building Department, Messrs. Wm. Wood and Son, Limited, are developing a nursery adjacent to their present premises at Taplow, where they are growing and raising alpine and herbaceous plants, including dwarf rock conifers, roses and hardy flowering shrubs. They have been fortunate enough to secure the services of Mr. A. Lynes, late of Messrs. Waterer, Sons and Crisp, as their nursery manager. They would be glad to have particulars of any rare and new plants that raisers and collectors may have for disposal.

THE annual general meeting and dinner of the Royal Botanic Garden (Edinburgh) Guild was held in Ferguson and Forresters, 129, Princes Street, Edinburgh, on the evening of Wednesday, September 8th, 1926, Professor W. Wright Smith, the president, occupied the chair.

After the business meeting members and friends, to the number of fifty-two, sat down to dinner. The guests of the evening were Mr. W. Thomson, seedsman and nurseryman; Mr. Jeffrey, the city gardener, and Mr. Wm. Austin, nurseryman.

WAKELEY'S Celebrated Hop Manure

(PATENTED)

THE ORIGINAL AND ONLY RELIABLE SUBSTITUTE FOR STABLE MANURE

AS USED IN THE GARDENS OF GREAT BRITAIN

DIPLOMA AND MEDAL, ROYAL INTERNATIONAL HORTICULTURAL EXHIBITION, 1912

DO YOU REALISE IT?

A large bag of WAKELEY'S PATENTED HOP MANURE at a cost of only 7/- carriage paid to your door (if within 25 miles radius of London, or at a trifling extra if beyond), GOES AS FAR AS A CART-LOAD OF STABLE MANURE, without any of the defects of the latter; gives better results, is easy and clean to use.

Every ounce of Wakeley's Hop Manure is of value to the soil, supplying the necessary HUMUS in addition to the valuable plant food. Worthless rubbish is not added to make weight (as is the case of some artificial manures advertised).

Thousands do realise it, the proof of this is the constant flow of UNSOLICITED LETTERS received from time to time in praise of the wonderful results obtained at such a moderate cost (see Booklet for selection).

BEWARE OF IMITATIONS.—Genuine Only in Our Marked Bags containing Guaranteed Analysis

ILLUSTRATED CATALOGUE giving full particulars and testimonials sent on receipt of postcard.

CASH PRICES (including bags):

Small (about 1 bushel)	3/-

AUTUMN TINTS in the GARDEN

AT the fall of the year nothing is quite so attractive in garden, woodland or shrubbery as those trees and shrubs which taking on their Autumn tints create splashes of gorgeous colour at a time when the flowering plants in beds and borders are becoming bedraggled and untidy.

Conspicuous amongst the shrubs which thus add to the beauty of the Autumn days, are the many lovely varieties of Berberis with their brilliant coloured foliage in shades of yellow, orange and crimson, to be followed a little later by equally attractive coral red fruits daintily hung on graceful branches. In Spring, Summer, Autumn or Winter these Barberries are always lovely, either with flower, foliage or berry, and for grouping in bold masses on lawns, by the side of water, on edge of woodland, or in shrubbery they have no equal. Our catalogue describing these and many other beautiful trees and shrubs for present planting will be posted free on application.

JOSEPH FISON & CO. LTD
IPSWICH

Notes from Maidstone.

PRUNUS DAVIDIANA

Many gardeners have planted this charming shrub only to find it die back after a few years. This, we think, is very probably due to the fact that we have not yet found the right stock to graft it upon. We are pleased, therefore, to be able to offer plants raised from seed of the White and Pink variety, small bushes at 3/6 each, which we hope will restore this valuable spring flowering tree to British gardens.

NEW HARDY CRIMSON BROOM

AT Chelsea Show (1925) the King said," That red Broom is certainly very striking." This was the new crimson Broom "Dorothy Walpole," which received the unanimous Award of Merit from the R.H.S. as well as other distinctions in London and on the Continent. Plants have been sent to U.S.A., Canada, Australia, New Zealand, France, Holland, etc.

In the Field, *a well known ex-Curator of Kew Gardens wrote: "The richest coloured Broom known is one named 'Dorothy Walpole.' It is as hardy as the common Broom . . . and is very free-flowering . . . the colour is rich velvety crimson . . . more attractive than any of the coloured Brooms yet seen." The colour far surpasses Cytisus Dallimorei, and the growth is as vigorous as C. Andreanus; it requires no special treatment nor any kind of protection whatever—just a hardy shrub for ordinary garden soil in any part of the British Isles, however far north.*

A Vice-Chairman, Floral Committee, R.H.S., wrote: "Everyone who has seen my plant has been astonished at its warm glowing red"; and from a lady in Devon: "I am so delighted with the Broom 'Dorothy Walpole.' It has done splendidly and is like a sparkling gem in the garden—one mass of flower."

NEW SEASON'S PRICES.

Strong pot-grown plants now ready for planting out, to flower in May, 7/6 each. Carriage paid rates to any station in Great Britain or Ireland: One plant, carriage paid, 10/-; two plants, carriage paid, 18/6; three plants, carriage paid, 26/-; six plants, carriage paid, 49/6; twelve plants, carriage paid, 99/-.

Coloured illustration sent on application if THE GARDEN *is mentioned.*

THE GARDEN

VOL. XC.—No. 2862. OCTOBER 9, 1926 PRICE TWOPENCE.

GARDEN RENOVATION

TOWARDS the end of the summer it is well to give a little attention to renovation work in the garden. Too often the hardy perennial subjects in the herbaceous border are allowed to go on year after year, the idea being that these plants can very well look after themselves and that any time bestowed upon them is more or less wasted. As a matter of fact, any herbaceous border calls for a large amount of consideration if it is to be entirely successful. The plants vary a great deal in the vigour of their growth and the stronger kinds are always likely to crowd out the less robust sorts; in many instances the latter may be the more desirable. In October one can see at a glance just what has happened during the growing season. The more robust varieties of aster are likely to have developed to such an extent that they are taking up far more than their share of room, while the perennial sunflowers are turning up in situations where it was never intended that they should be at all. As a matter of fact, if the bed has been established for three or four years, it is worth while considering whether the time has not come to have a complete replanting. Of course, the lifting and reduction of the biggest plants, here and there, may be attempted, but it is usually more satisfactory to make a complete re-arrangement. This will give an opportunity for the trenching and manuring of the bed to make good the nutriment which the strong plants have taken from the ground. Where a complete replanting of the border is not carried out an annual manuring is really a necessity. Well rotted farmyard manure or artificial fertilisers may be employed as top-dressings.

Of course, the actual replanting of the herbaceous border will not be taken in hand until later on. It is important to decide, however, what you are going to do before the plants are cut down. In the case of a large bed it is worth while making a rough plan and, on this, noting the specimens which require some checking. In certain soils some of the perennials grow much taller than in others, and it may be needful to remove these more to the rear of the bed. Then while you can still find out the colours of the flowers, attach labels to the clumps. It is far better if the plants are to be lifted to tie a label to the stem rather than rely on one pushed into the soil near the clump. It is most annoying, after digging up a mass of roots of aster, for instance, to find that you have not the faintest idea as to the variety with which you are dealing.

Then, again, certain subjects must now be moved entirely from their positions. Now is the time to lift all your gladioli, also any other tender plants which have been outside during the summer months. Do not deal with these subjects carelessly, but treat them with respect. The drying and storing of these summer-flowering plants is a most important duty and, if well done, the gardener will be amply repaid next season by another fine display of flower. Detailed instructions are given elsewhere in this issue regarding the storing of gladioli, and if all amateurs will follow these carefully there will be no reason why, next year, their show of gladioli should not be as fine, if not finer, than this year's display. Moreover, their stock of plants will, in all probability, have increased.

Roses, this year, have been particularly good, and a little time spent among the roses during the next few weeks will be amply repaid. Where space permits, a few new varieties may be added to one's collection. Be careful in your choice, however, and do not make a selection purely on the beauty of the bloom seen at a flower show. Be mainly guided by what sorts do well in your particular district. It is an excellent criterion on which to work. Not a few varieties have something against them, such as being prone to mildew or, as is the case with many pernetianas, a prey to that unsightly disease, black spot. Rely chiefly on well tried sorts, although they may be old stagers. After all, they are wanted for garden decoration principally. According to all the canons, all the necessary preparation of the soil and heavy spadework should be completed by the end of this month at the latest, and planting commenced immediately afterwards. The secret of good rose culture is to provide a soil which is of a holding nature. It must retain a certain amount of moisture in the heat of summer, and it is for that reason that a soil of a clayey nature is excellent for roses. Be careful in planting, which should neither be too deep nor so shallow that the plants will be blown over. A good guide is to place the point of union of the stock and graft at soil level or an inch or so below it, as often soil shrinkage in the beds leaves it slightly above the ground level. If attention is given to these few points, the planting of roses will present no difficulty to the beginner. Shrub renewals may also be undertaken now, and try, as far as possible, to plant a few which will provide variety over the year.

Although these remarks apply wholly to the flower garden, bear in mind that already consideration should be given to the planting of fruit trees next month, and that the time has now come to select varieties for future planting.

If these details of renovation and renewal are given the care and attention that ought to be devoted to them, then next year's garden will gain considerably in return.

HAVE YOU

¶ *Lifted the rooted layers of your border carnations? These should be potted up and stood in a cold frame.*

¶ *Taken cuttings of such bedding plants as antirrhinums, pentstemons, violas, pansies and calceolarias? Insert these cuttings in a frame containing sandy soil.*

¶ *Cleaned up your herbaceous border, lightly forked it over and given it a thin dressing of well decayed manure?*

¶ *Stored in a frost-proof shed your begonias, cannas, Salvia patens, etc.?*

¶ *Prepared and manured your ground for planting fruit trees?*

¶ *Made an autumn sowing of broad beans?*

¶ *Lifted and stored your carrots and beetroot?*

¶ *Protected your winter-greens by drawing up soil round the stems?*

Owing to the numerous letters which we have received from our readers asking the name of the variety of delphinium illustrated on the front cover of our issue of September 25th, 1926, we have pleasure in stating that it is the variety Monarch of Wales, one of the finest of the Wrexham strain sold by Messrs. Hewitts of Birmingham. We are indebted to Messrs. Hewitts for the flowers from which the illustration was made. At the same time we take the opportunity of thanking readers for the many kind letters of congratulation received during the past few days.

HOW TO ARRANGE HERBACEOUS BORDERS

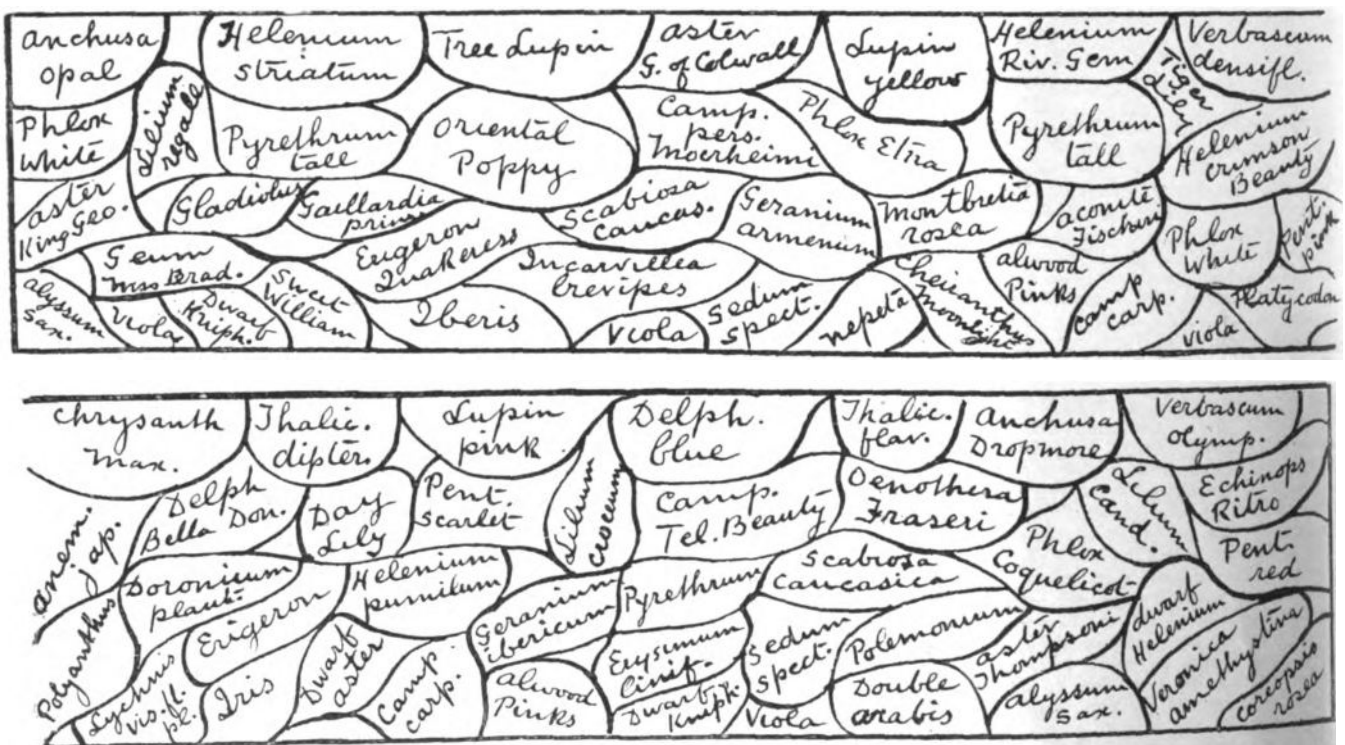
In this article, with its accompanying plan of a small simple herbaceous border, suggestions are given which may aid the amateur in the selection and grouping of plants to provide a border which will give the maximum effect over a long period. The work of planning and re-making the summer border should be commenced immediately.

THE average amateur's keenness for herbaceous subjects is generally limited by his space. He wants, or must have, a border that will give a pleasing effect the season through, and if this can never be the most satisfactory way of dealing with herbaceous perennials, it has its compensations. Such a border is always interesting and full of the charm of variety. It can, for the most part, be planned and planted right away in autumn. It involves a minimum of labour and expense, and if it does not yield a vast block of unbroken colour from spring to autumn, it can be quite gay enough to satisfy most of us.

As these suggestions are manifestly intended to give the beginner a "leg-up" in the difficulties he will usually encounter in making a start, the accompanying plan will doubtless prove helpful. Such a lay-out will perhaps not please everyone, nor will it be applicable to all soils and situations. Then we all have our individual tastes in flowers and their arrangement, and every planter should aim at striking a personal note. Here I can only propose a certain number of the hundreds of plants one has to choose from. These are selected, as I have suggested, with the view of obtaining an all-round interest, but the reader can delete some or add others as the fancy leads him.

The preparation of the border will always depend upon the condition and nature of the soil. Generally speaking, the ground should be well dug—trenched if necessary—and have worked into it a good dressing of really old manure or well rotted vegetable compost. This is especially needed along the back half of the border, and before the planting is done the soil must be allowed to settle naturally.

A glance at the plan will show that the taller plants are placed at the rear, but in the case of a border that has a walk on both sides, these would, of course, be down the centre. Then come subjects of rather lesser stature, while along the front are dwarf, or edging, plants. But, while this is a sound general rule, too much uniformity is not desirable. If some of the taller things are brought forward a little and lower ones worked back, a more pleasant variety in contour will be the result. Indeed, there are few features which afford such a striking note of character to a border as one or two moderately tall and stately plants among the lesser fry of the front row. Among these may be mentioned the dwarf kniphofias (early and late), Veronica gentianoides, Linum narbonense, liatris, Verbascum hybridum cupreum, V. nigrum, Camassia esculenta, Campanula grandis and Polemonium Richardsonii. Again, with the object of giving point and distinction to the border, such grassy-leaved subjects as the day-lilies, libertias and irises are most effective.



Into colour arrangement I need not enter, for reasons given; but if the planter desires he can, even in a border no more than about 40ft. long, so dispose all the taller plants that the stronger colours will be in the centre, with a gradation to the paler ones at each end. Or he may place the latter in the middle and work right and left to the deeper tones. On the other hand, in adopting something after the design of the plan, some regard must be given to the blending of harmonious colours and the avoidance of clashing tints.

Spacing is a detail which will have to be studied when treating each individual plant, or rather group of plants, for it will be wiser in most instances to put from three to five roots in a group, save in the case of big things like lupins, the taller verbascums and anchusas. But where there is any doubt it is wiser to be on the safe side and give too much room than not enough. In any event, but more especially during the first year or two, there will be spaces between each subject to fill up. These are, by way of illustration, indicated by blanks in the plan. Therefore, in addition to the herbaceous perennials with which the border is mainly planted, there is an extensive list of subjects which, if not strictly herbaceous, are quite permissible and extremely useful.

These fill-gaps are mainly biennials, annuals and bulbous plants, and while many of them are tall enough for the back row, they are often very slender and so take little room. To name a few, I never think a border is complete without some evening primroses of the large-flowered kind. The white, yellow and mottled foxgloves are also first-rate subjects, and Canterbury bells will often come in very useful. A few border chrysanthemums, which need not be put out until some of the earlier things are cut back, will always be welcome during the later summer and autumn, and at the same time groups of montbretias and the Cape hyacinth (Galtonia candicans), will do much to prolong the show of colour.

Then there are the spring bulbs, daffodils, alliums, ornithogalums, brodiæas and the like, which will go fairly well back, as will the late-flowering gladioli, antirrhinums and May-flowering (Darwin and cottage) tulips. These tulips are a most valuable addition to an herbaceous border, the long, slender stems rising among other plants to a height of 2ft. or 3ft., and the flowers, which last a long time, often going on to midsummer.

If the border is verged by grass, true herbaceous subjects can, if desired, be brought right to the front; but if there is a path, or stone edging, then one may go in for any of the various more or less prostrate subjects usually classed as rock plants. A few of these are included in the plan, but there are scores of others—campanulas, sun roses, armerias, alpine phloxes and pinks, æthionemas, veronicas, hypericums, tiarellas and heucheras. These give a charming finish to a border, and here, again, the planter will be able to indulge his fancy to almost any extent in the many comely little bulbous plants which go so well with these front-seaters. The inclusion here of such subjects as rock plants and bulbs may be unorthodox, but I know that in my own borders they afford a colour and interest I would not be without.

PLANTS AT THEIR BEST IN AUTUMN

This is the third of a series of contributions to THE GARDEN *by the well known writer on horticulture, Mr. A. J. Macself. It is really an enlargement of our "Worthy Plants" that has been such a popular features.*

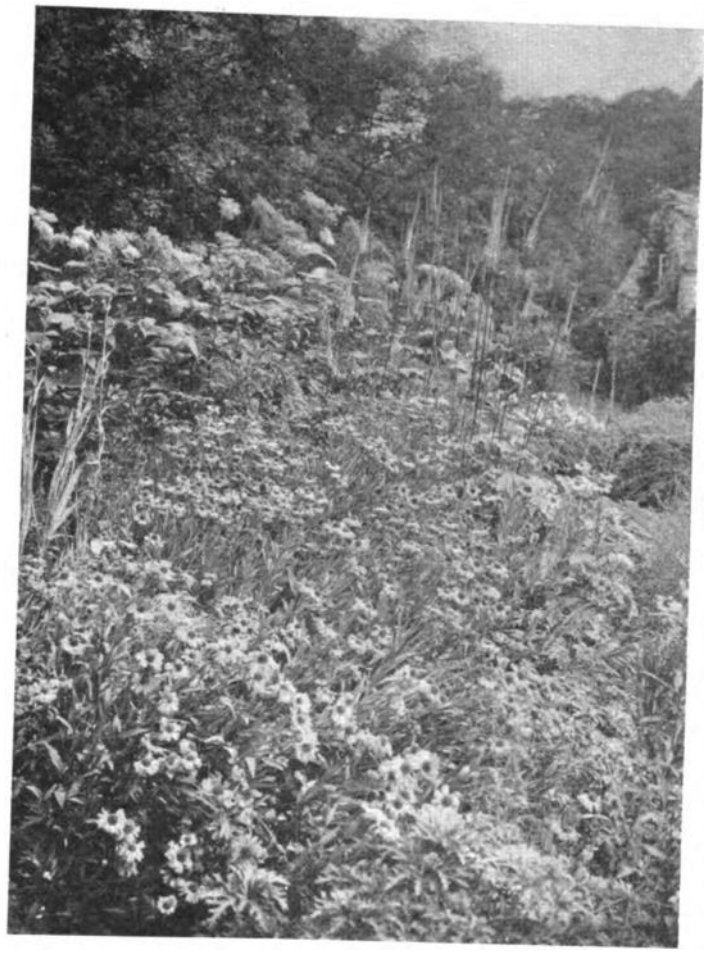
THERE is ground for lavishing special affection upon the plants which, having already given us of their best during the bright warm days of summer, are nobly making an effort to cheer us now that October's misty mornings tell us so plainly that summer is gone and winter is drawing near.

Potentilla Gibson's Scarlet.

Even yet this excellent shrub opens sufficient blossoms to bespangle its sprawling stems with scarlet as vivid now as it was in June. There are very few plants which maintain an unbroken succession of flowers for so long a period as this potentilla. It is no wonder there is always a scarcity of this plant, for it must fascinate many thousands who see it somewhere at some time during the period extending from the last week or so of May right into October. Two feet from plant to plant is not too much to allow when forming a colony or group in the foreground of a border, and the growths should be allowed to lie about just as they choose; it is a great mistake to tie or restrict the ever-lengthening stems in any way. Planted this month, on a patch of deeply dug and well manured soil, a dozen plants will provide a gorgeous display next year. It pays for liberal feeding with liquid manure.

Helenium pumilum magnificum.

By cutting closely back a few clumps of the bright yellow helenium when their summer flower-heads were going to seed the plants were induced to make fresh growth from the base. The stems are little more than half the length and substance of the first growths, but since mid-September they have thrown up as liberal a quantity of bloom as they gave in July. By keeping the September flowers cut right from the ground line, growth of new shoots has continued, and now, even after the latest of helianthus and rudbeckias have lost their charm, there is a bold show of clear golden yellow on these hard-worked heleniums. To persist in this treatment upon the same plants every year would, doubtless, wear them out; but it is a simple matter to treat half a batch one year and the other half the next.



GOLDEN HELENIUMS LOOK WELL IN THE AUTUMN BORDER.
By cutting back a few clumps now, fresh growths will be encouraged and perhaps a prolongation of bloom.

THE "WHITEWASHED" STEMS OF THE HANDSOME BRAMBLE RUBUS QUINQUEFLORUS.
These show up well in autumn and winter when planted against evergreens.

Cupressus macrocarpa lutea

This is not a plant of a week or a month—its extreme elegance is enjoyable every day in the year; but just now its clear yellow tint appears to be particularly bright, and it stands conspicuous among coniferæ, and especially in contrast to the darkest of green Irish yews. There was some talk of this fine conifer being less hardy than the type, but that is due to fancy rather than fact. Like its parent, it thrives best in sea air, and when it is not happy, geographical position seems to be the cause usually, and it is more a matter of longitude than latitude. The principal necessity is to be content to plant small young plants, and there can be little objection to this, for it is an extremely rapid grower.

Euonymus europæus.

This plant should never be despised because its name figures among the wildings of some few spinneys and woods of Britain, but it is not half enough grown in gardens. I have just seen a young "feathered" tree which, apparently, has never been touched with a knife, and right from the ground-line its delightful clusters of opened pods illuminate the whole tree with wondrous splendour. It is, indeed, as catalogues are wont to say, "a most attractive shrub which should be largely planted." The variety coccineus is of a more dazzling sealing-wax red than the type, and one or both should be ordered forthwith by all who are making new gardens.

The Whitewashed Bramble.

It is now that we can begin to appreciate the weird charm of Rubus Giraldianus or one of its close relatives Rubus biflorus or R. quinqueflorus. Its far-flung, formidably spined branches are white as refined chalk, and there is positively nothing to compare with the effect of a big, spreading bush growing before a background of sweeping cedars. One does not recommend the plant for trim town gardens, but it should be a conspicuous feature in many a wild garden.

THE BUSY MAN'S PAGE

Succession in Spring Bedding.

Some Suggestions.

A LITTLE thought expended on the combination of early and late-flowering bulbs, together with a judicious choice of carpeting plants, will ensure the beds and borders being gay from mid-March to the end of May. Here are some suggestions which will be found to work out satisfactorily:

1.—Early double Tulip Lord Beaconsfield (rose), Darwin Tulips La Tristesse (lavender-mauve) and Margaret (pale pink). Carpeting, pink double daisies. Edging of pale purple crocuses.

2.—Narcissus Golden Spur, Cottage Tulip Bouton d'Or (or Golden Crown). Carpeting, Wallflower Vulcan. Edging of Scilla sibirica.

3.—Early single Tulip Queen of the Netherlands (shell pink), Cottage Tulip Inglescombe Pink. Carpeting, Myosotis Sutton's Royal Blue.

4.—Narcissus Henry Irving, mixed Rembrandt tulips. Carpeting, single arabis. Edging, yellow crocuses.

5.—Early Tulip Thomas Moore Improved (brownish red), Narcissus incomparabilis Lucifer. Carpeting Wallflower Primrose Monarch. Edging Chionodoxa Luciliæ.

6.—Early Tulip Prince of Austria (red, shaded orange), Spanish Iris Thunderbolt. Carpeting, Cheiranthus Allionii. Edging, Muscari Heavenly Blue.

7.—Early Tulip Chrysolora (yellow), Darwin Tulip Dream (soft heliotrope), Cottage Tulip Moonlight (pale primrose). Carpeting, mauve primroses.

8.—Narcissus Emperor, Cottage Tulip Ellen Willmott (primrose, shaded yellow). Carpeting Wallflower Blood Red.

9.—Narcissus odorus (Campanelle), Cottage Tulip Millet (crimson) or Darwin Tulip Hambeau (deep crimson, blue centre). Carpeting, double arabis.

10.—Narcissus Tazetta Grand Soleil d'Or, Spanish Iris La Nuit or Heavenly Blue. Carpeting, polyanthus in shades of yellow.

11.—Early Tulip Cottage Maid (pink and white), Cottage Tulip Picotee (white, edged pink). Carpeting, polyanthus in shades of crimson and maroon.

12.—Early Tulip Pottebakker White, Narcissus Leedsii White Lady. Carpeting Wallflower Sutton's Orange Bedder.

In the last six schemes edging plants have not been included, but they can be added if wished.

The Foam Flower.

WELL proved and charming hardy plants are frequently overlooked because of the desire for novelty, whether the new acquisitions are as good or are inferior; but there are many old favourites which it would be almost a crime to neglect. Tiarella cordifolia, the foam flower, comes under this category. When well grown it is delightful, with its rather heart-shaped, spotted leaves and its spikes of white, feathery flowers, which have given it the popular name it bears. It is an excellent plant for the rock garden or border, but as it delights in a good supply of moisture, some rather damp spot might be found for it. It must not, however, be in too wet a place. There is room in most gardens for this lovely little plant, and as it is only a foot or so high it is as well adapted to the small as to the large garden. Plants may be raised from seeds, but it grows well from divisions made in spring or autumn. It grows satisfactorily in sun or shade.

Bulb Planting.

WHEN planting bulbs and corms of all kinds it is advisable to have a quantity of sand near by, a little of which can be utilised for placing below each bulb. The sand at the base of the bulb prevents rotting setting in due to the presence of continuous moisture and to a certain extent stimulates the formation of roots. After planting has been carried out a slight surface mulch given some time in November or December will be found beneficial in protecting the bulbs from severe frost, especially if they have not been planted deep enough.

A PLEASANT SPRING ASSOCIATION OF TULIPS, PEONIES AND GOLDEN ALYSSUM.

All three subjects can be planted now.

Runner Bean Tubers.

MOST people know that scarlet runner beans form large tuberous roots. As a matter of fact the plant is really a perennial, although in this country it is usual to treat it as an annual. It is worth while saving a few of the tubers to secure an extra early crop next year. Select some of the largest, taking care not to injure them with the fork. Then store in a box of dry sand, placing the whole in a frost-free place. These tubers may be planted about ten days before the ordinary seed sowing, and they will produce strong plants that will quickly come to the cropping stage.

Plant and Divide Your Lupins Now.

EARLY autumn and just before growth begins in spring, are the most suitable times to divide and replant lupins. Do not disturb your established lupins unless the soil in which they are growing has become exhausted or you wish to increase your stock by division. It is better to purchase and plant some of the fine new varieties which are now on the market, rather than disturb a clump of lupins which is flowering well. If replanting is necessary, lift the plants gently with a fork on a day when the soil is not sodden, and take care not to break off any of the fleshy roots. Prepare large holes in the border and replant the divided pieces firmly.

Glory of the Snow.

BULBS of this charming, early spring-flowering plant, Chionodoxa Luciliæ, should be planted as soon as they can be obtained. To display its full beauty it should be planted in bold patches; no conception of its true beauty can be formed when only seen as single bulbs dotted about, but the contrary is the case when planted in masses, and one can readily imagine what a wonderful picture it must make in its native land.

Good patches are delightful among rockwork or in the mixed border, but it is lovelier still when seen growing in grass in a position where it will not be over-shaded. Glory of the Snow is a most appropriate name, for it may frequently be seen in full flower when the ground is covered with a carpet of snow, and the blooms remain uninjured even in severe frosts.

Although it is sometimes recommended for indoor pot culture, it is not exactly suitable for that purpose. Even outside it appears naturally to flower rather irregularly, and this characteristic is more marked when grown in pots. Under cold-frame treatment it has proved most unsatisfactory, and it is not nearly so good as Scilla sibirica for pot work.

Echeverias—Winter Quarters

FOR the winter, and, indeed, until early spring, echeverias, those succulent plants still grown by many, need only to be kept free from frost and on the dry side, administering water only occasionally. Not always is it possible to find a place to meet their requirements (a frost-proof shed or room will do), and not infrequently they have to be accommodated in the greenhouse where heat is kept up for other things. It is then when trouble begins, as excitement is quite unnecessary and much moisture only tends to make them damp off or reduce them to a state understood by gardeners as "flabbiness." Often the winter requirements can be met by placing them in pans or boxes and depositing them in a dry frame having a south aspect. I have wintered them in such a quarter, but one has to be prepared to cover with mats on the approach of frost, also to keep a sharp look-out for slugs, which sometimes attack them. The main thing for echeverias is to keep them dry most of the winter. The advantage of growing in boxes in a frame is that they can easily be removed to other quarters should the winter be very severe.

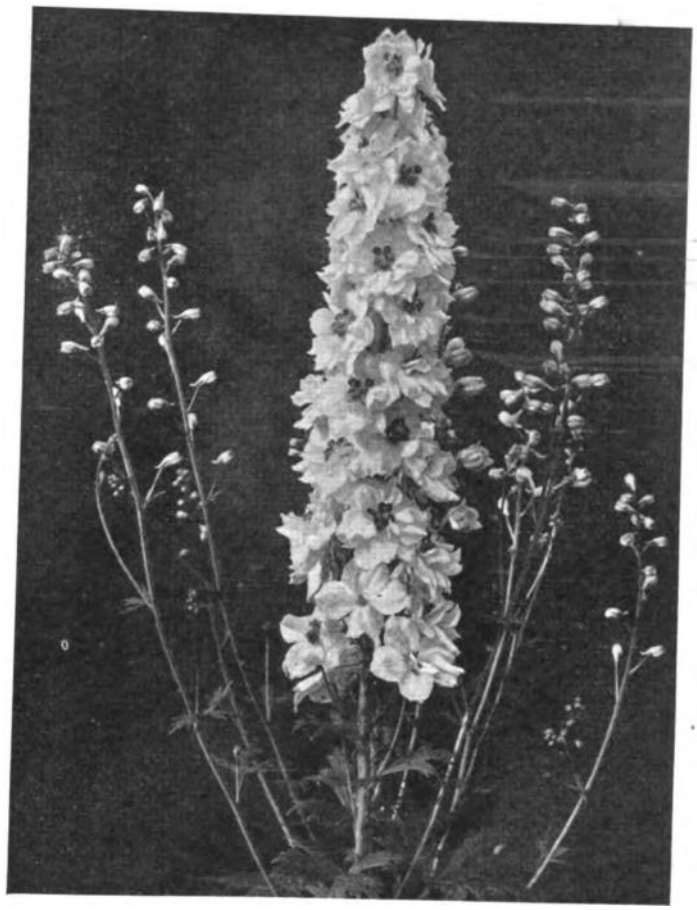
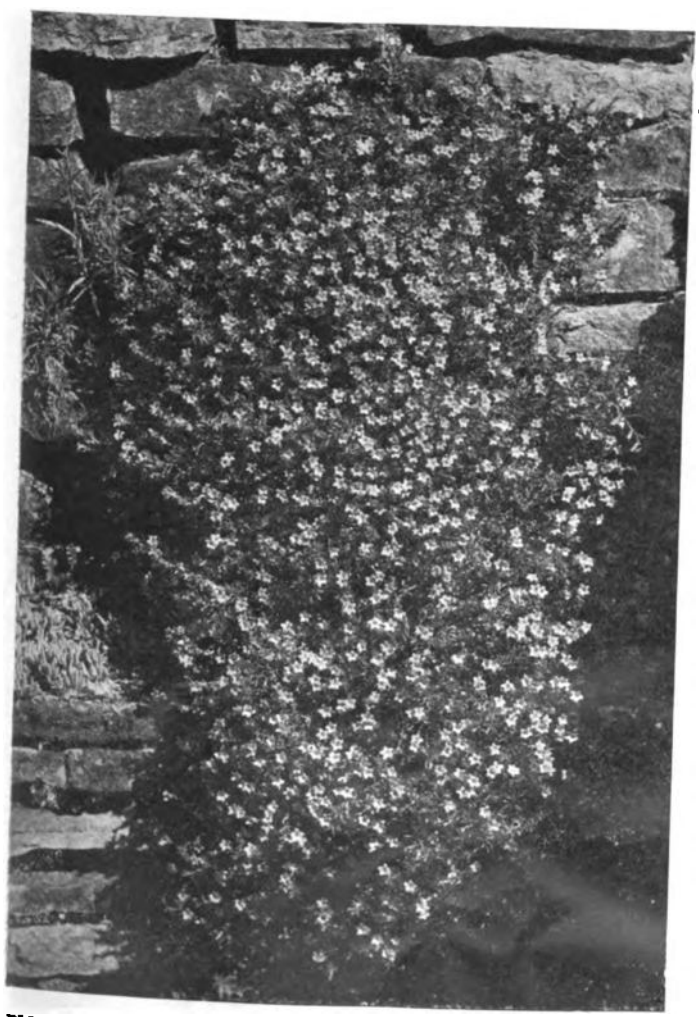
SOME BLUE FLOWERS TO PLANT NOW

WHEN planning an all-blue border, bed or corner in the garden, it should be borne in mind that if both pure blues and purple-blues are to be introduced, a great deal of care is called for if they are to live happily together. To consider the pure blues first, chief among the tall, back-row plants come the delphiniums, light and dark, ranging from the old favourites, Belladonna and Persimmon, to the newer Blue Boy, True Blue, Royal Blue and Queen of Bath, all of which are free from purple. Anchusa italica Dropmore variety, is a glorious colour, and if well treated will grow 5ft. high. There is also a more recent introduction, Pride of Dover, but it is doubtful whether this shows any marked superiority over the older kind. Then there is the seldom seen but very charming Baptisia australis, the False Indigo, which has pea-shaped flowers of a good blue shade; the great blue Himalayan poppy, Meconopsis Wallichii, a glorious plant growing 5ft. or 6ft. high, but which needs moisture and peat; the eryngiums, effective in any situation, of which E. planum is perhaps the freest from grey, although in other respects it is inferior to E. Oliverianum and Echinops Ritro Taplow Blue, which is more decidedly blue than the old variety of the globe thistle and grows tall. Neither the eryngiums nor the echinops, however, have any real claim to be classified among pure blues, but their glistening metallic tints accords admirably with the clear and definite blues of such things as Linums perenne and narbonense, Commelina cœlestis, Geranium grandiflora, Plumbago Larpentæ (this will do in semi-shade), Anchusa myosotidiflora—alas that it should be so beloved of slugs!—and Omphalodes cappadocica, a front-row plant this, but not a trailer as Blue-eyed Mary. There are very few really blue campanulas, although many are described as such by nurserymen. C. persicifolia is a blue tone of lavender, especially the variety Telham Beauty, but the nearest to true blue is the delicate, slender-stemmed C. rotundifolius, the garden variety of the wild harebell. Pentstemon heterophyllus is doubtfully hardy in cold districts, but if a warm, sheltered place can be found for it, it should be tried. Its flowers are certainly flushed at the base with soft, rose mauve, but their main colour is a clear, bright blue, and it may be counted among the best of the liason plants.



THE STATELY DELPHINIUM, ONE OF THE BEST OF BLUE FLOWERS.
They should be planted now.



BLUE FLOWERS LOOK MOST EFFECTIVE ON DRY SUNNY WALLS.
Here is the easily grown and attractive Lithospermum prostratum (Heavenly Blue) smothered in flower.

No flower is of a more beautiful shade of light blue than our native chicory, Cichorium Intybus. It is a straggling, untidy grower and has the tiresome habit of going to bed at an unreasonably early hour, but a big bush of it, 4ft. or 5ft. high, seen in sunshine at midday, when its myriads of sky-coloured flowers are all open, is a thing to be remembered. A band of either Gentiana acaulis, G. verna or G. sino-ornata, will make the most charming of edgings to a blue border or bed; but, unhappily, the gentians, especially the lovely starry verna, are tricksy sprites and will not thrive everywhere. For a raised rockery stone edging, the trailing Lithospermum prostratum Heavenly Blue is admirable; its colour is very rich, but its habit, in light soils at any rate, is rather unduly rambling.

There are some good blue annuals, myosotis, nemophila, Nigella Miss Jekyll, cornflowers (light and dark), and Phacelia campanularia, being among the first to occur to me. The latter is showy and has a long flowering season—always provided that it escapes the delicate attentions of the slugs! Convolvulus major and C. minor can both be had in dark and light blue, although neither can be relied upon to come true invariably, and Sutton's hybrid Nemesia Blue Gem deserves a place in the list, as also does the dwarf variety of the chickling vetch, Lathyrus sativus azureus. This climbs to a height of about 5ft. and has small, but brilliant, turquoise-blue flowers which look very pretty in a modest way, if the pea is grown in clumps on bamboos connected by strings down the centre of a border.

And there is the tiny annual sedum, S. cœruleum, despised by some for its insignificance, but very dainty for growing between edging—or paving—stones.

Of plants that, being on the border line between pure blue and purple blue, will help best to bring the two into harmony, the delphiniums are again the most important, as they are to be had in an infinite variety of shades, from pale sky blue to reddish purple, through beautiful tones of opal. Some of the eryngiums, too, are good "linking-up" plants and the same may be said, although not quite unreservedly of the aconitums. Of these last, the best are A. Fischerii, the

Digitized by Google

THE QUAINT LOVE-IN-THE-MIST, WHICH ALWAYS LOOKS WELL IN AN OUT OF THE WAY CORNER.
Nigella Miss Jekyll is one of the best varieties.

nearest to true blue and of medium height, A. Wilsonii and A. Sparkes' variety, the last two growing to a height of 5ft. or 6ft. There are no really blue lupins, but among those of both the polyphyllus and the arboreus × polyphyllus sections are several that have purple flowers shading to blue, while others—and very charming they are—are pure blue flushed with rose or pale gold. The hybrid Eastern Queen, for example, may be admitted in a blue border without an undue departure from consistency.

A plant which is not as much grown as in the past is the spiderwort, Tradescantia virginica cœrulea; it is a pretty shade of purple-blue and is excellent for a damp corner. Another good "old-fashioned" plant is Cupid's Dart, Catananche cœrulea, which flourishes in any fairly light soil in sunshine, and Centaurea montana does well—often rather too well!—under similar conditions. These three are all most suitable for the middle of a border of moderate width, growing about 2ft. to 2ft. 6ins. high. There are many campanulas in shades of lavender-blue and purple blue, ranging from the tall C. lactiflora (there is a strain of deeper colour which is preferable to the type), C. latiloba and C. latifolia, to the many alpine kinds which are delightful growing over a rockery-stone edging. Of these, C. Portenschlagiana and C. pusilla are, perhaps, the best of those most generally grown, but there are others almost as charming and quite as easy to grow. Platycodon Mariesii, that near relation of the campanula, is a very lovely shade of rich blue-purple. It should be planted in masses for effect as—in my garden, at any rate—it increases but slowly. The only really blue aquilegia—A. cœrulea and A. glandulosa are both blue and white—is A. alpina. It is not very reliable in this climate, but if it can be provided with a well drained soil with plenty of sand in it, and a warm, airy situation, it does well.

R. E. HEAD.

FOLIAGE PLANTS for the SMALL ROCK GARDEN

TOO frequently the value of foliage is deemed secondary to that of the flower. With some plants the beauty of the foliage is not seen until the flowering season is over, while with many others the approach of winter is signalled by brilliant coloration of their leaves. The following is a list of twenty plants which can be trusted to provide beauty at times when there is little to see in the small rock garden.

Achillea Kelleri.—A silvery beauty with delicately cut leaves and the purest of white flowers.

Artemisia pedemontana.—Another silvery treasure without the same beauty of flower, but well worthy of a place in any collection.

Berberis Wilsonæ.—For autumn colouring berberis are supreme. This is one of the dwarfest.

Cotoneaster adpressa.—Probably the most perfect habited of all rock shrubs, and with leaves which turn a beautiful shade in late autumn. The berries are delightful in their turn.

Dianthus cæsius.—Forms a beautifully neat mat of a wonderful silvery blue colour.

Erodium chrysanthum.—Pure silver with exceedingly charming flowers, the yellow colour being exceptional in a race of pinky tints.

Geranium argenteum.—Very well named and probably the best of its kind.

Juniperus communis compressa.—The cheeriest of baby conifers and universally beloved.

Juniperus Fletcheri.—Much bigger, though still a baby. The foliage is more attractive.

Picea pungens Kosteriana compacta.—This is the blue spruce and a matchless colour. It is far too seldom seen in rock gardens.

Potentilla fruticosa Vilmoriniana.—Grows rather tall, but its silvery leaves and pale lemon flowers make it a welcome addition to any rock garden.

Potentilla nitida.—A sun-lover whose leaves positively sparkle. It is, unfortunately, rather reluctant to flower.

Raoulia australis.—Probably the most beautiful carpeting plant in cultivation. The pure silver of its tiny leaves excites admiration.

Saxifraga cochlearis minor.—A splendid example of the diminutive encrusted saxifrage with most attractive flowers. It follows the contour of a rock like moss.

Sedum spathulifolium purpureum.—Here the foliage is an intensely deep plum colour and forms a wonderful foil to the burnished gold of the flower.

Sempervivum rubicundum.—Another wonderful colour which deepens as the season advances.

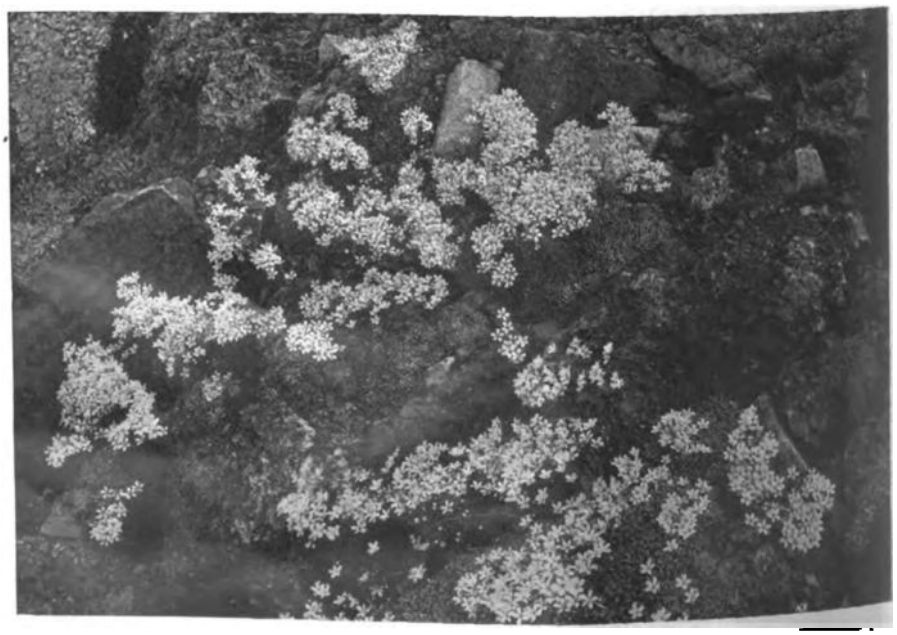
Senecio Grayii.—A pure silver plant, seldom seen, with a very charming yellow flower.

Teucrium aureum.—A silvery aromatic which seems to get daily more silvery when flowering has ceased.

Veronica incana.—The true plant is exceedingly beautiful and the leaves are pure silver. The flowers in their turn are of a splendid shade of purple.

Veronica Trehane.—Here we have golden foliage, a neat habit, and flowers of a pleasing shade of blue.

Much more could be said of the charm of foliage, and many other plants possess as great or greater charms: those enumerated are, however, in general cultivation, inexpensive, and not difficult to grow.



A CHARMING EXAMPLE OF A FINE ENCRUSTED SAXIFRAGE (S. COCHLEARIS) WHICH SHOULD FIND A PLACE IN EVERY ROCK GARDEN.

Digitized by Google

THE JOY OF MAKING A NEW G

By GERTRUDE JEKYLL.

In this article suggestions are given for the lay out of ground adjacent to a house built on a corner si site calls for unusual treatment in its design, and the arrangements and suggested plantings put forward by M. will be found most effective by readers who have a plot of ground similar to this in shape and size to

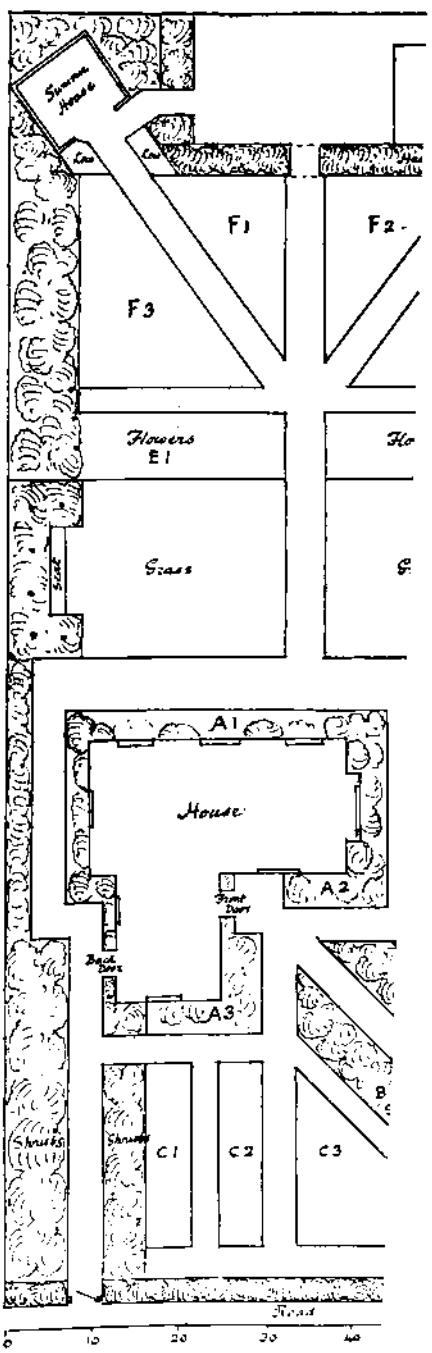
THE site of this house and garden is different from the more usual ones because it is at an angle of two roads and has a wider proportion. There is a step up from the pathway by the road to the segmental-fronted landing; the wall at the back having the same curve reversed. This is backed by a continuation of the evergreen hedge that encloses the property on the two outer sides. A diagonal path leads up to a small paved space by the front door; it will be all the better if this path can also be paved.

It is desirable that the planting on both sides, in B1 and B2, should be of shrubs, mostly evergreen, the better to secure the privacy of the two garden spaces D and C. The borders C1 and C2 would be for flowers; C3 may have an alternative arrangement of either flowers or, what may be better, small shrubs such as lavender and China rose: always a delightful combination. Or, if it is desired to have something simpler than these paths and borders, the whole could be a quiet space of grass, with evergreen shrubs keeping it private from the tradesmen's entrance.

To the north-west the large border D1 is for flowers, and D2 for flowering shrubs—lilac, philadelphus, weigela, deutzia, etc., with a few groups of plants of special interest, such as lilies and roses on the side facing D1. The borders close against the house are always best filled with something of shrubby growth; in the larger spaces there is nothing better than laurustinus and box, especially at the angles, where there is so often a draught. Where this occurs, the protection of a solid evergreen may make all the difference to the well-being of any tender shrubs that may come between, such as sweet verbena, hydrangea or one of the hardier fuchsias. With these and the addition of rosemary, lavender and the beautiful Olearia Gunni, and lower growths of santolina, stachys, dwarf lavender, catmint and the broad-leaved saxifrages, the borders would be well clothed for all seasons.

A wide path passes along the main south-west front, ending in a seat closely sheltered by a planting of yews. In time the yews may be encouraged to come forward over the seat when they have grown to a height of 7ft., so that they will eventually form a complete hood. A good space of grass on this garden front is divided by the path that runs straight down; on one side it will have a long seat protected and shaded by a planting of Portugal laurels. E1 and E2 are flower borders; tall plants at the back, or a backing of any of the flowering shrubs that do not take up too much space, will screen the pleasure garden from the useful but less beautiful vegetable beds marked F.

After the flower borders E, the two diagonal paths separating symmetrically will have a good effect: one of these leading to a summer-house. A thick hedge of green holly shuts off the garage and the space between it and the summer-house, which will serve for a place for burning dry rubbish and also for a rot-pit, a most useful thing in these days of difficulty : It is a rectangular pit 2ft. deep, w stuff, lawn mowings, weeds and all and most woody material, unlikely



be thrown. Whatever its size twice as long as it is wide, ar one end. After lying for six to the empty end and the bottc material, fit to be used in any

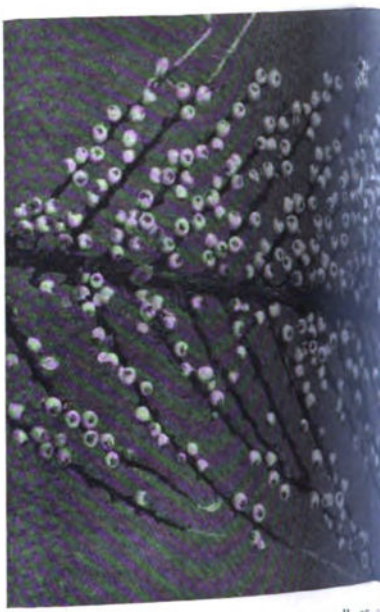
WHY NOT HAVE AUTUMN

SOME BERRIED SHRUBS

All gardens are made the more brilliant in autumn by the inclusion of a few of the best of our berried and autumn-tinted trees and shrubs, and at this time of year preparation should be made to ensure a bright display next autumn by planting a few of the most handsome kinds this season. Many of them are, indeed, shrubs of dual purpose, with their bright floral display in spring and an equally decorative show of fruit in autumn, and the amateur will find that the beauty and charm of his garden will be greatly enhanced by the introduction of even a few for the sake of autumn effect.



ONE OF THE "SAILS" OF

E SALMON CORAL FRUITS AND GOLDEN SPINES OF BERBERIS SUBCAULIALATA.

llustrations on these pages represent five very useful genera ried shrubs. The berberis are by far the most popular and e for general purposes. Their bright red or blue fruits in se of some species are most attractive, while the foliage, nd spines lend further beauty to the plant. Many of the viburnums carry crops of handsome fruits, and V. Opulus luteo is one of the finest, even although it is only a better f our native guelder rose. Pyrus Eleyi is one of the most ntal of fruiting pears. It makes a small but elegant tree neat habit, dark almost purple foliage and its large, hand- uits. Another brilliant berrier is the stranvæsia, excellent ub borders. Cotoneasters, of which C. horizontalis is representative, are undoubtedly shrubs for the amateur.

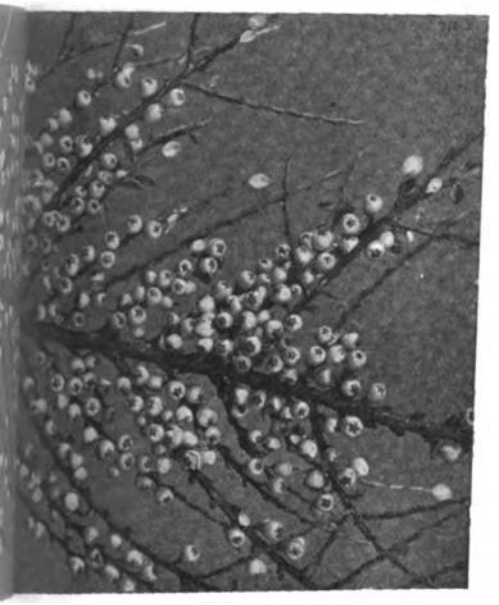
...BS WORTH PLANTING



...COTONEASTER HORIZONTALIS.

The majority of them are easy to grow and amateurs should find little difficulty with them, once the initial trouble of planting is completed. Almost all are hardy and accommodating subjects and grow equally well in the cold rigorous climate of the north or the more kindly conditions of the south. Certainly in southern gardens they berry more freely and form one of the most attractive charms of many a small garden around London. Plant a few of the sorts mentioned in these pages and you will find the expense and trouble amply repaid by the brilliance of their autumn display.

THE FRUIT AND KITCHEN GARDEN

ring Ground for Planting Trees.

THER fruit trees are grown on a all or a large scale it is of the highest nce that the ground be well pre- The trees are to remain many years, be, in the same place, and although and root-pruning can be done while young, this work is not easily carried en they are older. If the ground der grass, peel off the latter and store future use, mainly as a top-dressing years hence to encourage roots to ear the surface. Trench all soils ft. deep, leaving the subsoil below top in a lumpy condition. If the ground n neglected and the soil is full of ts of weeds, clear them out now— not any better opportunity. If the very poor prepare manure for putting a surface mulch round each newly tree. If the soil is rich, prepare or a similar purpose. Planting in ber instead of spring means, practically, gained.

s for Fruit Trees.

RE any fruit trees are planted in the hard the necessary stakes for their should be prepared. Where a single used, as may be the case in positions at sheltered, one stake will be suffi- nd it should be driven firmly into near the centre of the opened ground the tree is placed there, then there be any damage done to the roots of er. In very exposed positions it is ntage to provide three stakes for each hese stakes are driven into the ground a triangle, to meet near the main s and fastened to the stem securely, ch material under them as will prevent lising of the bark. When three stakes d the young tree is held securely the wind, no matter from which n it may blow. Let the stakes be hooth and neat, but strong.

Fruit Trees.

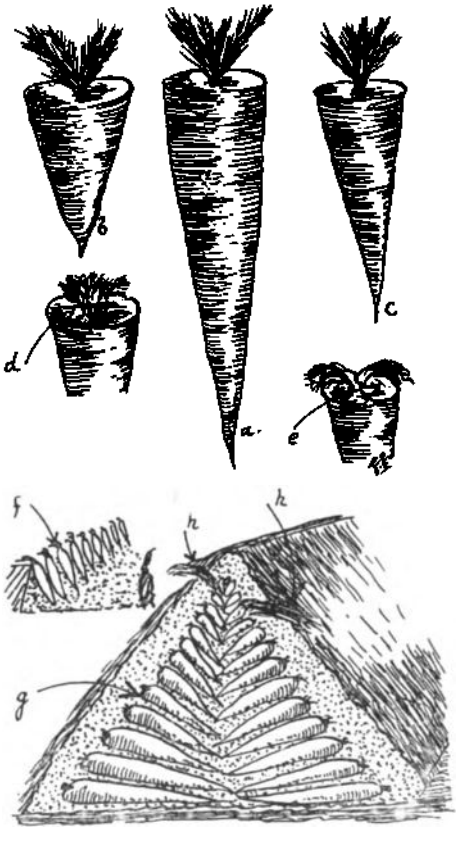
present is a very good time to make necessary arrangements for planting ar to walls in November. It is, also, le time to consider the question of n of tree to plant. I am quite sure hateurs who possess wall space do e the most of it in this respect. From time I see a lot of valuable wall wasted. The planting of fan and ally trained trees is neglected and nting of cordons almost ignored. would urge all those who possess grow cordons of both apples and pears, ne of the best varieties of plums. s are not difficult to manage, and they e finest fruits. If, by chance, a tree small gap only results, and this can aced quickly and at a small cost. ge fan-trained specimen fails, a big made and, for several years, while nches of a new tree are filling it up, ace is wasted. Furthermore, we can any more varieties, when the cordons ferred, on a given space, and, again, ail to crop satisfactorily, others succeed ld us fine fruits. On high walls the may be trained upright; on low ones gle of 45° to secure length of cordon. may be trained as double cordons, les and a few varieties of pears; but cordons of the latter, generally, are t.

ment of Wall Fruit Trees Now

irst thing you should do is to examine soil 1ft. below the surface. The soil er near a wall sooner than it does middle of the garden. Unless the position is a low, damp one, carefully loosen the surface crust and apply water liberally. Cut out every bit of unwanted wood and very forcibly syringe the trees and the whole of the wall surface, too, to clean the branches and clear away any insects lodging in holes in the wall.

The Treatment of Spring and July Sown Carrots.

DURING the past few years gardeners have paid very close attention to the raising of late vegetables—those that mature well from seeds sown in July. Of course, they are the naturally early maturing varieties, and afford the cultivator ample supplies for winter use. Now, too, we are concerned about the harvesting and storing of the roots to the best advantage. Where the carrots are grown in a sandy soil they may be left



in it later than in cold, heavy loam, as there is not so much danger of splitting, decay and damage from frosts. It is unwise to use ordinary soil in which to store carrots, as earthworms always do a lot of harm by eating holes in the roots. There is not this danger if pure sand or fine ashes are used—the first-named for preference.

Lift all the roots with the aid of a garden fork so that they will be intact. At *a*, *b* and *c* three types are shown, and the best way of storing them. The tops should be cut off rather close to the crown as shown at *d*. If left on, as shown at *e*, it is quite likely that the long tops will decay and cause the crown to do so, too. The types *b* and *c* may be stored close together in a sand-bed as shown at *f*, and type *a* as shown at *g*. Wisps of straw, fixed as shown at *h*, *h*, will afford ample ventilation. Store in sand and cover with straw.

Ripening Tomatoes.

WHEN the weather really breaks up it is much better not to allow the green tomatoes to ripen on the outdoor plants. These fruits are not likely to grow much more, and it is wiser to gather them. If allowed to remain on the plant they are quite likely to start to rot. Cut the fruits as far as possible in clusters, with a liberal amount of stem. It is a great mistake, as is often done, to hang the green tomatoes in the sun. This will make them shrivel badly, so that many of the smaller ones are hardly fit for eating. Hang the clusters in a shaded and even a dark place, and the fruits will take on a fine red colour and become perfectly ripe. Tomatoes ripened in this manner are hardly to be distinguished from fruits freshly gathered.

Preparing Vegetables for Forcing.

THE work connected with the forcing of the earliest vegetables is most interesting. I have, just lately, been requested by some beginners in my own district to explain how the forcing of certain vegetables is done. They are not content with their summer work among their crops, but wish to have early ones by means of forcing. Now, like fruit trees, vegetables must be sufficiently ripened to force well. Rhubarb and seakale should have thoroughly matured their leaves, so that the crowns are large and firm. If there are weeds on the beds, hoe them up and very carefully clear them away. Do not use a garden rake among the crowns of the vegetables, but pick up the weeds there with the hand and use the rake in the alleys between the rows, then the crowns will not be bruised. Chicory should be examined now, weeds and faded basal leaves cleared off the ground. It is only the strong roots that will yield large succulent tops. The strongest asparagus plants, too, should be duly noted and marked if they are to be lifted for forcing. Sift some soil and keep it dry in readiness for packing round the chicory, rhubarb and seakale roots. Prepare any necessary boxes, tubs or pots, and also a nice heap of litter covered from the rains.

A Watercress Hollow.

A CONTINUOUS supply of crisp watercress may be obtained from the garden in this way. In any fairly open position dig out the ground in the form of a hollow. The opening might be 4ft. or 5ft. across, with a depth at the centre of about 9ins. below the ordinary level. Loosen the ground well and then insert the watercress cuttings 3ins. or so apart. The cuttings are taken from bunches of watercress and practically every piece will grow. As long as the weather is at all inclined to dryness, pour several buckets of water into the hollow each day. The cuttings root rapidly and are soon in full growth. Frequent gatherings are likely to encourage a vigorous shooting, so quite a small hollow on the lines described will supply the needs of the average household. Now and again it is a good plan to scatter a little rich soil as a top-dressing to the watercress and a sharp look-out should be kept for any weeds.

Cleaning the Asparagus Beds.

USE and not abuse the asparagus plants and they will yield very remunerative crops for many years. At this time we have the ripening tops, and soon it will be necessary to trim the beds and put them in order for the winter. It has been a very common practice to put on a thick coat of wet manure in the autumn. This is wrong treatment, as such a coat of wet manure keeps the soil and roots cold. There is not any need to feed the plants during the winter, as this should be done in the summer, and all you have to do now is put on a thin layer of half-rotted litter which will act as a warm winter covering in the true sense.—G. GARNER.

WHAT OUR READERS SAY

A SMALL SUBURBAN GARDEN.

SIR,—I am sure many readers of THE GARDEN will be pleased to see it in its new form and under a new price, and if the present standard is maintained it will prove of the most valuable assistance to all amateur gardeners like myself. I am pleased to see that it is the intention to run a series of articles with designs on the planning and planting of gardens by Miss Jekyll, and feel certain that such articles will be most helpful. I have been much interested in the two articles which have appeared, and in response to your request send along an illustration of the herbaceous border in my garden. This year it has been a perfect mass of colour from June on until the present time. This autumn some renovation work will need to be undertaken on the basis mentioned in a recent article in THE GARDEN, to reduce the size of the individual clumps and also to introduce new subjects. It may be of interest to readers to see what success can be obtained in the growing of herbaceous plants in a suburban garden near London and the effective display they provide during the summer months. The other illustration shows how effective baskets or pot plants are when placed round the house. The zonal pelargoniums have been much admired with their bright trusses of blooms and their handsome foliage. Many more amateurs might be encouraged to grow them near the house where they are so decorative.—G. R.

BASKET AND POT PLANTS MAKE A MOST EFFECTIVE DISPLAY NEAR THE HOUSE DURING THE SUMMER MONTHS.

WINTER ACONITES.

SIR,—I am consumed with envy of "R. E. H." able to buy her winter aconites by such hundreds, nevertheless I sympathise deeply with her, because I have the same horrid Bath soil. Only worse, probably, since my garden is on a stony hillside, a thin coating of soil over millions of stones. Perhaps the aconite trouble would cease to afflict if she got a large load of leaf-mould and made rockeries with it. I have done so, using the sandy parts of the native soil, with a little rotten cow manure and a dash of stable manure, also a small proportion of weathered ashes from the hot-water furnace. This mixture seems to suit aconites very well, also hepaticas, the nemorosa anemones, hardy cyclamens and crocus species, all of which are impossible in the staple lime dust. Unlike loam, you get quite a large quantity of leaf-mould to the lorry load, as it is so light.

I cannot resist breaking a friendly lance with anyone who recommends Scutellaria baicalensis. This brute from Lake Baikal, wherever that may be, entirely ruined a choice rockery for me, and, as a weed, has more vigour than gout weed. It spreads with incredible rapidity after pretending for a season, or perhaps two, that it is a pretty and harmless little thing, with charming blue flowers. It makes a dense mass of hard roots, which nothing short of deep digging, sifting and a bonfire on the spot will get rid of; and even then you meet it several yards away, getting up steam to destroy another area. In short, it is a regular land Azolla caroliniana. I should like, if I had unlimited space quite away from the flower garden, to put it and Convolvulus tenuissimus, with two or three others any gardener can think of, on a bank together, and see which would win.—M. L. R. W., *Bath.*

A WELL ARRANGED HERBACEOUS BORDER IN A READER'S SUBURBAN GARDEN.

"FAMILIES" AND "VARIETIES."

SIR,—These terms, and particularly "variety," are often used by gardeners in quite a loose and vague way. Family is the modern name for the natural order, *e.g.*, ranunculaceæ. Ranunculus is a genus (anemone another genus), bulbosus one of the species of ranunculus; and the term variety is given to "a sort or modification subordinate to species" (Dr. B. D. Jackson), *e.g.*, Anemone nemorosa var. cœrulea, or to some garden-raised variation other than a hybrid. Both species and varieties should remain constant under cultivation, or they are unworthy of further denomination.—H. S. T.

GINKGO BILOBA FROM SEED.

SIR,—I wonder if many of your amateur readers have raised Ginkgo biloba from seeds. In a garden I visited last week, the owner showed me a small tree which he raised from seed he collected and brought home himself. Three seeds were sown, only one germinated, this is now, at three years, about 2½ft. high, and well established in its permanent quarters. —B. W. N., *Hereford.*

THE GRASS OF PARNASSUS.

SIR,—There is no native plant, to my mind, which can give such a wealth of bloom and for such a long period, as the Grass of Parnassus (Parnassia palustris). It can be seen at its best during the latter part of August and early September. The glorious white single flower born on a solitary stem stands out among the short grass in marshy places on nearly all our Scottish hillsides. We do not find it on the plains nor on the hill tops, but in marshy places on the hill slopes. The flower, somewhat reminds one of the snowdrop, with its pure white petals and delicate veins. It does not droop its head like the snowdrop, but stands erect, proud sentinel of the fading summer.

Although, as the name implies, it is a plant of our upland bogs and marshes, it

Digitized by Google

can easily be cultivated in our gardens, provided it is grown in partial shade and given abundant water during the summer months. —G. S., *Edinburgh.*

A RECORD IN DELPHINIUMS?

SIR,—It would be interesting to hear through THE GARDEN, if this has been a record year for delphiniums. One specimen here reached the height of 10ft. 2½ins. and had twenty-nine spikes on it. The accompanying illustration of this handsome specimen may be of interest to readers of THE GARDEN.—R. H. LAIDLER, *Durham.*

NAMES OF EARLY POTATOES.

SIR,—I have been interested in potato growing for many years and was greatly surprised to read Mr. W. Grant's statement in THE GARDEN, September 18th, page 528, that Victory is now masquerading under the name of Duke of York. This is certainly an admission. If growers are growing Victory under the belief that they have Duke of York—they therefore cannot tell the difference. The name Duke of York was given to this variety before that of Victory. Then why have both names? I should like to ask Mr. Grant to describe the botanical difference, if there is any, between Duke of York and Victory.

I certainly do not wish to cast any reflections on the raisers of new varieties of potatoes. Everyone who is raising new and improved varieties, especially varieties which will stand the immunity test, virus diseases and blight, is doing a service for all mankind.

May I also ask Mr. Grant why Victory has not taken the place of Duke of York as a commercial potato, when it is claimed by him to be an improved variety. At least one seedsman advertises Victory as being similar to Duke of York; that, again, is an admission.

A HANDSOME CLUMP OF DELPHINIUMS.

Mr. Grant mentions that Victory is the result of a cross between Duke of York and Fyvie Flower. Now, I am satisfied that Fyvie Flower is Duke of York, so that what Mr. Sim did was to cross Duke of York with Duke of York and the result has been, not a new variety, but Duke of York again. I should like heartily to congratulate Mr. Grant and all northern growers on being in such a fortunate position in having their stocks of potatoes free from all virus diseases.

For many years I have been on the lookout for a disease-free plant of Duke of York, and have travelled the greater part of Scotland, including Deeside, but so far have failed to find a single specimen. I have seen many stocks fairly healthy, but not absolutely free from virus diseases. Holland, I believe, is the only country where one can see Duke of York free from the virus disease called mosaic. May I suggest that Mr. Grant supplies the Board of Agriculture with a stone of his so called Victory and I will gladly send a stone of Duke of York; or, as he has no faith in the Board, I will make a sporting offer. Mr. Grant to supply a stone of Victory seed and I a stone of Duke of York, both lots to be planted side by side in a nursery or garden convenient to both, say Aberdeen, Mr. Grant to appoint an arbiter and I will do likewise, the examination of the plants to take place about the end of July or early August and the result published in THE GARDEN.

Mr. Grant does not seem to be familiar with the work which is carried out by the officials of the Board of Agriculture. He suggests that the Board encourages the raising of new early varieties. This, of course, is far from the point at issue. I have nothing in common with the Board of Agriculture, still, I do like to give honour where honour is due. The Board is encouraging and protecting the raisers of new varieties of potatoes. A visit to East Craigs, Corstorphine and Philpstoun, will, I think, convince Mr. Grant.—GEO. STUART.

[The correspondence on this subject is concluded.—ED.]

HINTS WORTH REMEMBERING

This is the third instalment of Hints that have been received from our readers in response to our request. There seems little doubt, judging from the numbers that have reached us, that this will prove a most useful feature of THE GARDEN *in future. We hope, therefore, that all our readers will assist to make this page as valuable as possible by sending in their Hints, the result of personal observation and trial, and so help the gardening public in general. Hints which will be specially considered as worthy of a prize will be those that are seasonable as well as interesting and apply particularly to duties that can be carried out in the garden at the present time.*

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Each must be sent in on a separate sheet and must not be more than 300 *words in length.*

THE HALF-GUINEA HINT.

Prolonging the Supply of Roses.

In cutting roses, either for the house or in removing dead ones, it is important to cut back a good distance, at least 6ins. and past any spent shoot, to a visible bud in the angle of the leaf. This is practically summer pruning. The tree responds at once by sending out a flowering shoot, which flowers in a marvellously short time. By adopting this plan of never "nipping" off dead flowers, my rose garden has been a continuous mass of colour since June, with no dull period and I shall have roses as long as weather permits. —M. R.

How to Get Rid of Carrot-Fly.

If you have a bed of carrots and you suddenly see with dismay the carrot fly has been at work and its maggots have started on the roots of the carrots, get some *unslaked* lime, mix it with water at the rate of two handfuls of lime to four quarts of water, and with this mixture water all those carrots showing signs of maggot, and you will save your whole bed; do it when the ground is moist or water with clear water first; I have watered the whole bed sometimes with lime water if there has been signs of maggot in more than one patch.—(MISS) E. F. CORNISH-BOWDEN.

How to Deal with Big Beetroot.

If beet has grown so large that it exceeds the dimensions of the pan, the colour may be preserved by cutting in half, the bleeding being sealed by applying a hot iron to both cut parts. It is not generally known that large beet can be roasted in the oven, but the flavour is not so good as when boiled.—(MRS.) E. E. PEARSON.

Propagation of Clematis by Cuttings

Cuttings from most clematis may be struck in spring, by means of short, young shoots with a piece of old wood attached to form a heel. The sappy shoots alone will not strike, as they shrivel too quickly. Insert cuttings in a cold frame to ensure success and give air when necessary to avoid damping off. They can also be struck in summer (June or July), but frame light should be shaded from fierce sun. Cuttings require to be kept fairly moist, and succeed best in loamy soil, mixed with sand. A little leaf mould may be added, but too much seems to cause the callus to rot. Pot up when struck, as this ensures good root growth.—V. W.

Spring and Summer Bedding Together.

The following method I have found most successful and labour saving. Get your bed prepared for planting, then first fill up your bed with Canterbury bells, planting about one foot apart, and between these plant tulips. The tulips give a fine display in the spring, and can be lifted when they have done blooming and dried off. The Canterbury bells continue to grow on and fill the bed, and give a good display right through the summer. A tulip I like for this method is Prince of Austria.—W. T.

Propagation of Hollies by Cuttings.

Perhaps the following hint will be of some service to readers of THE GARDEN. The best time of the whole year (from personal experience) is to take cuttings the first week in December, inserted under a bell-glass in the open. Ilex insignis, a most difficult subject, I was singularly successful with. Several people tried with me in friendly competition, but failed. At various times of the year I have experimented, but the latter part was most successful.—J. M.

Digitized by Google

AUTUMN SOWING OF SWEET PEAS

Few amateurs realise the value and importance of making a sowing of sweet peas during the next fortnight. If the seeds are sown outside and the weather conditions remain fair over the winter months, then fine healthy specimens for planting out will be obtained by March next year.

ALTHOUGH autumn sowing has repeatedly proved the more satisfactory method, three or four times as much sweet pea seed is still sown in the first three months of the year as in September and October. Probably this is because so many growers do not realise the comparative hardiness of the flower or fight shy of the additional trouble which an autumn sowing in pots in a cold frame entails.

I assure readers who may be doubtful, that the enhanced results more than justify the little time spent in looking after the seedlings during the winter months. Some may say, "What advantage is there in sowing sweet peas in the autumn?" While I admit spring-sown plants may give good results, I am confident that, on the whole, there is no time like September and October for sowing. In the first place, autumn-sown sweet peas come into bloom much earlier; further than that, they often continue to produce good flowers after the spring-sown ones have finished. Their hardier constitution and much more extensive root system promote more vigorous growth, tending to render them less liable to contract disease, more responsive to judicious feeding and the better able to withstand droughts, particularly in late spring. The actual flowers are larger, of better quality and, for some reason not very apparent, their colours are a trifle more "solid," more brilliant. The last named is not exaggeration, but plain fact, as anyone with an eye for colour may prove to his own satisfaction. No wonder almost all successful exhibitors in all parts of these islands now rely entirely on autumn-sown plants.

An Easy, Economical Method.

While I would never recommend the sowing of the newer and more expensive varieties right out in the open ground where they are to flower, a row or two of a good but inexpensive mixture of Spencer or "frilly" varieties treated in this way may well be a source of pleasure and a generous provider of cut bloom for the house from early June until late August. An ounce of seeds (which should cost no more than one shilling) will be ample for a row 8yds. to 10yds. long. It is wise, of course, to sow on well prepared soil that has previously been deeply dug or, better still, bastard trenched and liberally manured, for sweet peas produce huge quantities of flowers and need a deep, rich rooting medium to give of their best. The rows should run from north to south, and be unshaded from the sun by trees or buildings. Just make drills with the side of a hoe 1½ins. to 2ins. deep (as for culinary peas), sow the seeds and, after covering them in, dust soot all over the surface. The actual time of sowing will depend on locality, but the end of September to the third week in October is wide enough a range, the later date for the south of England, the earlier for Scotland and the north. By sowing as thickly as already advised, an ample margin is allowed for possible losses from frosts, birds and other pests, and if it is found that the plants are too thick in the row in spring, it is a simple matter to thin them out. Where the unwelcome attention of birds is feared, the young seedlings—when they appear—may be protected either by the well known wire pea guards or by a few strands of black cotton stretched along the rows just above them. Slugs and snails may be kept in check by sprinkling lime or soot (not both) or finely sifted ashes on each side of the rows in the young stages. Later on, when the growth is more woody, slugs will not touch them. About the beginning of November give the young plants support by means of twigs about a foot high. This will not only prevent them from blowing about, but will

THE LARGER PLANT WAS SOWN LAST OCTOBER, WHILE THE SMALLER WAS SOWN AT THE END OF FEBRUARY.

It will be seen that the former has been pinched and has thrown out two strong side basal shoots.

afford no small measure of protection from frosts. No other attention will be necessary until their permanent supports are placed in position in the spring.

Cold Frame Treatment.

This method is advisable when dealing with comparatively expensive seeds, for it is less risky than an outdoor sowing and more economical. Late September is not too early a date for the north of England and Scotland, while the end of October is time enough on the south coast. A cold frame is the only protection the plants need during winter, although a cold greenhouse may be used. Pots are preferable to boxes for the reason that they are, as a rule, better drained and the seedlings can be moved at transplanting time with less likelihood of damaging their roots. I find 48s pots a convenient size, but smaller ones answer the purpose just as well. Long "thumb" pots containing only one plant are often used when a limited number of plants are required. Boxes should be at least 5ins. deep, but not more than 9ins. As a potting medium, any good garden soil will do if not too rich and fairly light. The addition of well decayed leaf-mould and silver sand will render the more "clingy" soils sufficiently porous. Crock the bottoms of pots or boxes in the usual way to ensure ample drainage and to prevent the roots finding their way out. Sow the seed ½in. deep, allowing roughly 2 sq. ins. or 3 sq. ins. of surface space to each seed. Label each pot or box, or each batch of pots, as the case may be, with the name of the variety, afterwards taking care at all stages that no mixing of varieties occurs.

Necessity for Rapid Germination.

One's aim should be quick, even germination with only just enough moisture in the potting soil to effect this and not enough to cause some of the thin-skinned varieties, such as the whites, lavenders, blues and creams, to rot during germination. Some of the black-seeded kinds, such as Charity, Hebe, Warrior, etc. (not the coffee-coloured seeds, such as Hawlmark Pink, George Shawyer, etc.), are thick skinned and, comparatively speaking, impervious to moisture, and a percentage of their seeds will lie in the soil, or even in water, for weeks before swelling. Such seeds should have a very tiny portion of their seed coat removed with a file or sharp penknife on the side opposite to the "eye" to ensure a quick germination. Dress the soil of the frame with a soil fumigant such as Apterite or Vaporite to get rid of any stray wireworms or slugs, and to avoid frequent watering plunge the pots to their rims in soil, peat, ashes or fibre refuse. This will also protect the roots from frost. Mice may be troublesome, so do not fail to set a "breakback" trap or two on top of the pots. Keep the glass framelights on until the plants appear through the soil, then immediately remove them altogether, only replacing during frosty or very wet weather. The frame should be in an unshaded position, open to sunlight all day as far as possible, but if protected by a wall or building on the north or north-easterly side so much the better.

Hardy and Sturdy Growth Essential.

Give the young plants perfectly hardy treatment throughout the winter months; water very sparingly. Net the frame if birds are a nuisance. To encourage the formation of strong basal growths pinch out the tops of the plants as soon as three pairs of leaves have formed and keep them upright in their pots or boxes by inserting small twigs. Above all, do not "coddle" the seedlings in any shape or form. Hardy, sturdy growth is essential, and if you forget all about them and leave them to take their chance with the framelights off all through the winter, they will pull through nine seasons out of ten. The procedure I have outlined in detail is very simple and will most certainly ensure strong, healthy plants for transplanting to their flowering quarters in March.

C. H. A. S.

NURSERIES OF THE BRITISH ISLES.—V

MESSRS. KELWAY AND SON OF LANGPORT.

THERE are few gardeners the world over who are not acquainted with the name of Kelways of Langport. In the eighties and nineties of last century their place in the horticultural world as leading growers of plants had been firmly established, and from then up to the present day they have greatly added to the lustre of their name by the prominent part which they have played in the enrichment of our gardens by valuable contributions in the shape of the gladiolus and of the delphinium as we know them to-day, as well as in other directions no less valuable.

They were the pioneers in the gladiolus world, being the first firm to give us the large-flowered varieties, which they produced from 1870 onwards, and more recently by presenting to the horticultural world, as a result of their crossing, the now famous Langprim strain of gladioli. Again, it was largely owing to the enthusiasm and insight of the founder of the firm and Mr. William Kelway that the delphinium was taken in hand, developed, improved and made the popular plant it is to-day. In spite of these excellent credentials, however, they, as a firm, are probably best known as the leading peony growers in this country and probably in the world. In almost every corner of the globe where gardens flourish, their fame as peony growers is recognised—a monument to their energy and activity in the improvement and development of this fine herbaceous flower.

June is the month of the peonies, and those who can spare the time should certainly not miss a visit to Langport to view the magnificent colour display presented by the peony beds in their full beauty. The huge flowerheads in all their opalescent shades provide a perfect riot of colour which is made all the more brilliant and effective by the carpet of heavy foliage, which makes an admirable foil. Some of the blooms are of mammoth dimensions, and when one finds four or five clustered on the one stem the decorative effect can well be imagined. Many will have seen and admired those shown by Messrs. Kelways at the fortnightly shows at Vincent Square; but the peony, to be seen at its best and in all its nobleness of character and beauty, must be viewed as it grows in a bed. And one will not only see beds of them at Langport, but fields of them. When grown in a mass, after this fashion, the plant retains its bushy habit and only requires staking when the site is an exposed one. Moreover, where staking has to be considered, it can be done almost unnoticed owing to the plant's heavy crown of leafage. It is here that the amateur will realise how effective and decorative it can be if grown properly, and what a blaze of colour it will add to the June border in the garden if included in the planting scheme. Nowadays, it is not the flower of the specialist. True, there are many high-priced varieties, largely due to the fact that it takes a considerable time before the raisers can work up a stock of the one variety; but, on the other hand, there are many low and medium priced sorts which contain, from the point of view of colour shading, all that the amateur grower wants. Such varieties may be found in Lady Alexandra Duff, Kelway's Rosemary, Princess Olga, Sunrise, Lemosil, among doubles; while among the singles there are Pink Pearl and Duchess of York. All these will prove good and reliable kinds and, when once given their position in the garden, require little or no further attention and give freely of their lovely blossom year after year.

More recently, Messrs. Kelways have been specialising in pyrethrums and the changes now recorded in the character and colour of the flower are almost beyond belief. Every year sees the birth of new shades of colour, and those flowers which appear to the growers eye to be striking and unique and show improvement on existing varieties are carefully selected and grown on through a number of generations till a pure line results, which makes it safe for the amateur to go ahead. Few amateurs realise the number of years which the nurseryman has to wait till a variety proves itself, and all the while it

has to be looked after like some pampered child.

It is these years which are the testing time, and which, if successful, result in plants coming true to colour and type from seed, which the amateur sees as novelties either in the nursery bed or on the exhibition table. This production of new varieties is no easy or inexpensive task, and an insight into this line of work would make many amateur growers more tolerant of the efforts of our nurserymen, who are continually striving to raise the standard of our plants. In pyrethrums, many excellent crimson shades are to be seen at Langport, and the gardener who wishes bold splashes of colour in the border in early summer should certainly grow a few choice kinds of these newer pyrethrums. They are graceful both in flower and foliage, and never seek to get out of hand, an important point to be considered in choosing border plants.

These and many other flowers are to be seen on a June visit to Langport. We noted many fine new seedlings among the delphiniums, of good size, colour and habit of growth, many of which will ultimately find their way to the exhibition stand and there enhance still further the reputation of Messrs. Kelways as a firm of renown.

The beds of gladioli presented a picture of perfect health during our visit, and it is the products of these beds which have given us the fine displays of this first-rate border flower staged by the firm at the August and September shows. It is now, when the gladiolus is coming into its own as a garden flower of the highest merit, that we realise the debt which the gardening world owes to the enterprise of Messrs. Kelway for the part which they have played in raising a strain of this flower which has done much to bring about its present popularity. That they still take as keen an interest in the well-being of the flower is shown by the fact that the firm offered a challenge bowl to the National Gladiolus Society to be awarded to the best group of British gladioli grown by an amateur and staged at the show at Burton-on-Trent.

It has been largely through the efforts of the present owner of the firm, Mr. James Kelway, that our present ideas of colour arrangement and schemes in the herbaceous border have been evolved and perfected, through the introduction of Kelway's Colour Border, which provides a harmony of colour throughout the summer months.

Almost every branch of horticulture is catered for in some way or other. Vegetable trials, as well as flower trials, are carried on with marked success. The interests of the firm are catholic and widespread, as can be seen at once by a visit to the nurseries. The amateur gardener who can afford the time will find himself well repaid by a visit. He will not only learn a great deal about plants, if his visit is timed to coincide with the most effective floral display, but he will come to appreciate the more the efforts of such pioneers of the horticultural world as Messrs. Kelways and what they have done for English gardens and gardeners.

A BED OF MESSRS. KELWAYS' STRAIN OF HARDY PYRETHRUMS.
These look well in the border when massed in clumps.

OUR SERVICE BUREAU

Though so many subjects are dealt with in each issue of THE GARDEN, *it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, there is always information available from a staff of expert contributors and consultants; and there is no charge for this. It is one of the additional means of service which* THE GARDEN *is glad to render to its readers.*

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope and the coupon, that will always be found in each issue, shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2.*

We have selected the following enquiries, with their answers, as being of more general interest, and therefore worthy of publication.

Montbretias.

I have not been very successful with the culture of montbretias, which makes me think I am not treating them as I ought to. My garden is situated in open country near the town, and I grow them in clumps.—T. RILEY.

Montbretias prefer a rich, well drained soil in a rather sunny position. Varieties should be planted in early April, and the more tender ones generally lifted in October, the corms being dried and then stored in sand or a frost-proof shed over the winter. When in active growth occasional waterings should be given in dry weather, with liquid manure to act as a stimulant. They may either be grown in beds or in the border in a sunny aspect.

Wintering Geraniums and Fuchsias.

In window-boxes and vases outside we have ivy-leaved geraniums, which were bought new this spring. As we have no greenhouse, I am wondering what to do with them during the winter. Would it be any use potting them up and standing them in a frame or stables, or would it be better to take cuttings in a cold frame? Also we have some fuchsias which are not the small-flowered kind. Is there any method of preserving them?—E. M. G.

Take up and pot the ivy-leaved geraniums, reducing the roots and shoots—that is, cut them back one-third—and winter them inside a window, anywhere safe from frost and excessive damp. Be careful not to overwater. The fuchsias may be stored in the stable during the winter. Do not water after the first application until February, when new shoots will begin to grow.

Unsuccessful Figs and Vines.

I have a fig tree growing against a wall in a heated vinery. It appears healthy and has plenty of fruit on it, but none of the figs have come to perfection. Some grow larger than others, but most of them just the size of a small plum.

Another glasshouse contains seven old vines. Each have a few bunches, but shanking has been very bad among them. The borders are both inside and outside, the inside border being 24ft. long and 12ft. wide. The vines seem deeply planted, and I was thinking of lifting them and replanting in fresh soil. Do you think this will cure them from shanking, as I think that it is the border which is causing the trouble? The house is heated.—A. F.

When the young shoots are about 6ins. long, pinch off the ends and young figs will soon form. Any good garden soil will be suitable, but a nice chalky loam is ideal. Do not overcrowd the shoots, but do not cut them off—thin out while young. Admit air freely in nice open weather.

Undoubtedly the vine roots are deep in a cold subsoil. Lift them and replant nearer the surface, using a good fibrous loam, builders' mortar rubble and finely ground bones. Do this work at the end of October and only one portion of the border in one year. Do not allow the roots to get dry; while out of the soil syringe and wrap them in wet mats.

"Broken" Tulips.

If tulips which have "broken" are planted, will the offsets from these be also striped, or is there a chance of their returning to the original whole colour? In cleaning off my tulip bulbs I find that frequently I cannot avoid rubbing off the outer skin, thus leaving the bulb white. Can you tell me whether this does any practical harm?—E. S.

Your question raises a very difficult point regarding the breaking of bulbs. It is almost impossible to say when a bulb thus broken will revert to a pure type or when

BULBS
what to plant when to plant

Cultural notes of the greatest value both to professional and amateur gardener form a special feature of the new illustrated bulb catalogue issued by John Waterer, Sons & Crisp, Ltd.

A rigorous system of selection is followed at the Nurseries so that the purchaser receives none but bulbs of tested strain, inherently vigorous and therefore suitable for forcing and planting.

John Waterer Sons & Crisp Ltd

—for bulbs, plants and seeds of tested strain

a pure bulb will break. Changes in the soil condition seem to be responsible to a large extent, but even then evidence goes to show that this alone is not entirely the cause. Provided that the inner part of the bulb is not in any way damaged, the disturbance of the outer skin should not do any harm regarding the flowering of the bulb, but in future try to prevent, as far as possible, this injury to the outer skin.

Diseased Roses and Wistaria.

The diseased rose is on my house and is a fair size, but owing to the disease, which appears to be black spot, it is rapidly dwindling. Can anything be done to cure it? (I believe spraying is the only hope.) Almost beneath this rose is a very fine daphne, name uncertain, but supposed to be a cross between fioniana and neapolitana. Situated in an angle of the wall, it is about 8ft. high by 5ft. across, and in full flower now; in fact, it flowers for months and is finely scented. The rose leaves help to make a mulch for the daphne, and any spray or treatment must be innocuous to it. The wistaria leaves are also diseased apparently. It was only planted this spring out of a pot, and has made excellent growth and is still doing so. Another one within 12ft. is perfectly healthy. As I have been trying for years to persuade wistarias to grow on this house, and these two at last are away, I do not want to destroy the apparently diseased one if I can help it. Aspect in both cases, rose and wistaria, south south-east, soil peaty sand, typical heather soil. The wistaria was given a prepared home with the best soil we have and cow manure below. The rose is old and planted long before I came here.—L. J. T.

The rose leaves have the appearance of being affected by orange rust rather than black spot. The orange rust attacks the plants earlier in the season, and at that time—early June—the foliage should be syringed with a solution of sulphide of potassium, one quarter-ounce to the gallon. All fallen leaves should be carefully gathered and burned. Apply a rather stronger application of the sulphide now—after the leaves are gathered—then the drip will do some good, killing spores on the surface of the soil. Syringe the wistaria with "Abol" according to directions and surface mulch now with loam and leaf-soil, equal parts. Has the soil been well watered during the summer months?

A Shrub for Filling in a Gap.

I want to plant a fairly quick-growing flowering shrub, evergreen and bushy habit, not less than 7ft. in height, to fill a gap between fence and summer-house. The situation is south-west, but owing to the shade of the house gets little sunshine before noon. I had thought of Choisya ternata or Eucryphia pinnatifolia. Would these be suitable, and could they be grown together at, say, 4ft. apart?

Do you think Lonicera sempervirens would be successful on an archway facing west? I am about five miles out of Manchester and the soil can be made suitable.—S. M.

We should suggest Choisya ternata for the position you mention. Eucryphia pinnatifolia is a very slow grower, and you would have considerable difficulty in purchasing it 7ft. or 8ft. high, whereas Choisya ternata is very quick growing. Why not try Berberis stenophylla, with its weeping, arching branches. It would look well in such a position. Lonicera sempervirens should prove successful on an archway facing west.

Peach Trees from Seed.

We have in the garden the ornamental peach P. persica Clara Meyer, and this year for the third time it has fruited one peach. Is it worth while planting the stone? And if so, should it be cracked or otherwise treated before planting?—E. H. D.

Peach trees seldom come true from seed, and we think it highly improbable that by sowing the stone from the fruit of the ornamental peach you will raise a tree of any great value. Most seedlings are decidedly inferior to varieties grown. It is not difficult to get the stone to germinate, and the seedling would, no doubt, soon grow into a large tree. The stone should be taken from the ripe peach, dried and then sown in sandy loam in a small pot. The pot should stand out of doors all the winter, and in February or March it should be examined and the outer coat of the stone lightly filed along the edge, so that the seedling will have no difficulty in breaking it when germination commences. Often enough even this filing is unnecessary, the seedling breaking the covering without difficulty. When large enough to handle the seedling can be repotted, placing it in good loam, where it will grow rapidly, and may be planted into the open ground by the following autumn.

FURTHER NOTES ON HOLLAND PARK SHOW.

OWING to the extensiveness of this fine autumn show and to the great pressure on our space, we, unfortunately, were unable to mention all the chief exhibits in our report. We feel that several of those omitted ought not to be overlooked, for they were particularly meritorious and also of special interest at the present time, as excellent perennials which can be planted now were on show. Mr. W. Wells, jun., had an exceedingly fine group of herbaceous flowers which he brought from his nurseries at Merstham. The majority of his perennials which he exhibited are suitable for inclusion in a herbaceous border of modest dimensions. Aster Royal Blue (of rich deep purple blue), Aster Little Boy Blue (a dwarf semi-double Michaelmas daisy with clear blue flowers), the large-flowered crimson Pyrethrum Harold Robinson, Achillea Cerise Queen and Viking (a salmon pink phlox) were all good tall-growing perennials exhibited. The three following rudbeckias were also noticeable: purpurea with its uncommon blooms of crimson purple, nitida Herbstonne of yellow colouring and Newmanni with its conspicuous black eye in the centre of its golden flowers. Mr. Wells also showed his new double Gypsophila Bristol Fairy.

Another group worthy of mention was that of Messrs. Whitelegg, who staged a collection of all the finest modern Michaelmas daisies. Asters of the Nova-Anglia as well as numerous varieties belonging to the Novi-Belgii group were included.

The outstanding exhibit of fruit was staged by Messrs. Bunyard, who showed bunches of grapes grown on outside vines as well as countless varieties of apples and pears and plums. The Barnham Nurseries exhibited nearly sixty varieties of apples, while Messrs. Stuart Low had a collection of apples, with fig trees in pots placed behind them.

The fruit exhibited staged by Messrs. Daniel Brothers consisted chiefly of apples but pears, plums and grapes were also included. On the whole the fruit exhibits were of a good standard, in spite of the fact that this season has been an exceedingly bad one for fruit.

TRADE NOTE.

Messrs. W. Atlee Burpee and Co. would like to announce to our readers that seeds of their sweet pea novelties may be obtained from all seedsmen throughout the country and not only through wholesale houses, as stated in their advertisements.

LIFTING GLADIOLI

NEITHER the large-flowering nor primulinus gladioli are hardy; consequently, like dahlias, they need protection from frost during winter. The general tendency is to leave the corms in the ground too long, thus laying them open to the risk of rotting, particularly on heavy soils. It is not too early to dig them up a fortnight or three weeks after they have finished flowering. Lift them gently with either a fork or spade, taking care to keep each variety separate. It will be found that two, and often three, new corms will have formed in the place of the one corm planted (a new one at the base of every flower stalk sent up), while numerous little corms, generally known as bulblets, will appear around their bases. The old corm, like an old shrivelled potato, is attached to the base of the new ones. The whole plant—foliage, new corms, old corm and bulblets—should be hung up in an airy outhouse or in a greenhouse until withered and perfectly dry. This drying will be complete in ten days or a fortnight, and the stems should then be cut off about half an inch above the new corm, and the old one at the bottom broken off and thrown away. The treatment of the bulblets I will leave for a moment. After the new corms have been trimmed in the above manner, they are ready to be stored. A fairly dry (but not warm) and frost-proof position should be chosen, and they must not be put in a bag on top of each other, but laid out thinly on shelves or in trays. Potato trays are ideal, where a quantity is to be dealt with. There is nothing difficult about storing gladioli corms; simply lay them out thinly after drying in some frost-proof place, not damp and not too warm, till planting time in March.

Treatment of Bulblets.

Is it generally realised how easily and how quickly gladioli may be increased by means of their bulblets? I think not. Given ordinary treatment, the majority of bulblets from the large-flowering varieties bloom their second year, a few perhaps the first; while in the case of the more precocious primulinus hybrid varieties, a large number will bloom the first year—that is, the year after they have formed. Consequently, it is a decided waste to discard bulblets, particularly if they be of new and expensive varieties. Some varieties of gladioli produce large quantities of bulblets, others very few indeed. It is not uncommon to find upwards of sixty on one plant of what we should term a "good propagator." When lifting the plants, care should be taken not to knock or rub off the bulblets; then, when the plants have been dried off as already described, the bulblets—which are really little corms—will readily pull off. They vary in size from that of a small sweet pea seed to that of a large culinary pea. Store them in the same frost-proof position as the corms, but it will be found convenient to use little bags which can be hung up rather than trays. Cardboard boxes also answer the purpose admirably. Again may I emphasise the advisability of guarding against mixing the varieties together; each should be carefully labelled, for it is so much nicer to grow each kind separately. The bulblets will keep true to name and colour, and a large stock of any variety one particularly likes can be obtained within a very few years.

I recommend the following after-treatment. In mid-March, draw drills with a hoe and sow the bulblets just as you would sow culinary peas, at the same depth but a trifle more thickly, for it must be admitted that a small percentage of them will fail to "germinate" the first season. Keep them clean by frequent hoeing, but otherwise let them look after themselves until the late autumn.—C. H. A. S.

BULB MANURE

is both a Plant Food and a Soil Pest Destroyer

THE "Ferry" Bulb Manure is the result of many years of experiment where bulbs are grown to perfection. It is composed of all the constituents required for the healthy growth of bulbs. It acts as a soil pest destroyer, and ensures freedom for the bulbs from all insect and fungoid pests, which are the cause of so many failures.

In the open, use 2 to 3 ozs. per square yard when preparing the soil, for pots work ½ to ¾ lb. to each bushel of soil.

PRICES—Carriage paid, for cash with order—
7-lbs. 2/-; 14-lbs. 3/9; 28-lbs. 7/-; 56-lbs. 13/-; 1-cwt. 22/-

Agents wanted throughout England for "Ferry" Specialities.

The BRITON FERRY CHEMICAL & MANURE Co, Ltd. (Dept. E), Briton Ferry, S. Wales. (Est. 1886).

The Cultivation of Tobacco—No. 5.

Harvesting

THE Tobacco Harvest commences at the end of July, when the plants are harvested and threaded on long poles.

Mule carts are used to convey these poles to the curing barns.

The average crop is about 700 lbs. to the acre, but only a small percentage of this will ultimately produce the Rich, Ripe Virginia Leaf used in the making of

PLAYER'S

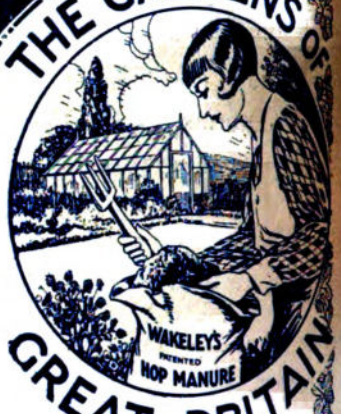
WAKELEY'S Celebrated Hop Manure

(PATENTED)

THE ORIGINAL AND ONLY RELIABLE SUBSTITUTE FOR STABLE MANURE

AS USED IN THE GARDENS OF GREAT BRITAIN



DIPLOMA AND MEDAL, ROYAL INTERNATIONAL HORTICULTURAL EXHIBITION, 1912

DO YOU REALISE IT?

A large bag of WAKELEY'S PATENTED HOP MANURE at a cost of only 7/- carriage paid to your door (if within 25 miles radius of London, or at a trifling extra if beyond), GOES AS FAR AS A CART-LOAD OF STABLE MANURE, without any of the defects of the latter; gives better results, is easy and clean to use.

Every ounce of Wakeley's Hop Manure is of value to the soil, supplying the necessary HUMUS in addition to the valuable plant food. Worthless rubbish is not added to make weight (as is the case of some artificial manures advertised).

Thousands do realise it, the proof of this is the constant flow of UNSOLICITED LETTERS received from time to time in praise of the wonderful results obtained at such a moderate cost (see Booklet for selection)

ILLUSTRATED CATALOGUE giving full particulars and testimonials sent on receipt of postcard.

CASH PRICES (including bags):

Small (about 1 bushel)	3/-
Large (about 4 bushels)	7/-
5 Large	33/9
10 Large	65/-
20 Large	120/-

Carriage paid by Pickford's or to any station within 25 miles of London, including delivery if within free delivery radius of Railway Company; 6d. per bag extra for every 50 miles or part beyond. Maximum extra charge Great Britain, 2/6 per bag.

WAKELEY BROS. & CO., LTD.

75a, BANKSIDE, LONDON, S.E.1

Small Orchards

No matter how small or large the orchard, it pays to use Stictite Tree Banding Compound.

Winter Moth rises from the soil early in October or late September, and the females (being wingless), at once crawl up the tree trunks in order to deposit their eggs in the branches.

By banding the trees with Stictite in the autumn you can prevent the eggs being laid, and so avoid having to spray for the caterpillars in the spring.

1 lb. of Stictite will do 9 to 12 trees of about 8 in. diameter.

½-lb. 1/6 (post 6d.); 1-lb. 2/9 (post 6d.); 2-lb. 5/- (post 9d.); 4-lb. 10/- (post 9d.); 7-lb. 17/6 (post 1/-).

Greaseproof Paper, 5 ins. wide: 6 yds., 2d.; 12 yds., 3d.; 25 yds., 6d.; 50 yds., 9d.; 100 yds., 1/6; 200 yds., 2/6.

Write for Descriptive Folder.

Stictite is sold by Nurserymen, Seedsmen, Florists, Ironmongers, Chemists & Stores. If any difficulty, please write to Abol Limited, 9, Beltring, Paddock Wood, Kent.

Stictite

Recommended for Roses, Bulbs, all other Flowers and Fruit Trees.

Notes from Maidstone.

CAPE PLUMS.

This group of Plums is descended from Prunus salicifolia, a Chinese species, but the exports from South Africa during the winter have led to the name given above. Not hardy enough to fruit outside in this country, they are most interesting orchard house plants in pots or trained on walls, and we offer three varieties: Abundance (Burbank), golden yellow and red; Botan, garnet red—the best flavoured; and Shiro, golden yellow, of enormous size. All are rather early ripening. Bushes and Fans are 7/6 each.

NOTES OF THE WEEK.

Your Help.

IN an article that appeared in our issue of September 25th, attention was drawn to the importance of readers and contributors pulling together. We hope that by co-operation we shall make THE GARDEN, not only pleasant and instructive to all gardeners, but an absolute necessity. This co-operation has been touched upon several times previously in the paper and it is to be hoped that old readers will not think it amiss if attention is drawn to its importance once again.

The old days of what might be called stilted gardening, are over and done with, and the cultivation of plants by rule of thumb methods have more or less disappeared, as gardeners realise more and more that plants respond according to individual treatment. In other words: it is easy to grow most plants fairly well, but much more difficult to have your fruit and vegetables and flowers of first-class quality, and the latter is what all gardeners should aim at. That is where your help and co-operation are so useful. Many readers by their own foresight and ingenuity have evolved methods, entirely their own, by which they are eminently successful with some plant or other. As there is no profession or hobby so generous as horticulture, will you not give of your knowledge for the benefit of the gardening fraternity in general? This is already being done in the space devoted to our "Hints from Readers," but that space is devoted to potted tit-bits of information, whereas your contribution may require more room in which to describe your discovery. Short articles and notes are always welcome and they will be paid for not only materially, but also in kind; for in other parts of the paper you may be able to read, perhaps, a note from another contributor that explains just why you have not succeeded so well as you might with this or that plant.

In fact, it is the aim of THE GARDEN to become the clearing house of all horticultural information, and to be a paper in which everyone has a chance to discuss his successes and failures. The editorial staff exists solely to co-ordinate and prepare every item of gardening information for publication. Let us judge if your information is of general interest, and do not bother about a literary style; it is the information that is important. We ask you to help your fellow gardeners by sending in contributions on your experiences on every phase of gardening. It is by this means that our gardens and the cultivation of our plants can be improved. We hope that THE GARDEN is proving more useful week by week.

Early Weeding.

THIS year has been a bad one for weeds in many parts of the country, so much so that much time has had to be expended in extra weeding that might have profitably been spent in doing other garden work. Gardens that have suffered worst are those in which weeding has been left in abeyance for too long. In fact, this year has proved the importance of weeding early in the season, particularly in new ground. It must be remembered that many weeds, such as the pestilential bishop's weed, seed very rarely, but are terrific runners underground. It is next to impossible to remove every inch of root, however carefully the soil is dug over so the longer it is left to grow unchecked, the stronger is becomes. On the other hand careful hand weeding or hoeing, by cutting off the vegetative growth, soon weakens the plant. Another point in weeding early is that few weeds go to seed; they are cut before they reach the flowering period and so their reproductive powers are checked. This is particularly the case, of course, with annuals. Weeding is practically over for the season: but this is a good time in which to point out the importance of early weeding. It is certainly the case that many of the weeds that in some cases have almost taken control of some areas of garden, could have been eliminated by a rigorous attack earlier in the season. It is often a good plan in a new garden, where the complete layout cannot be completed in one year, to utilise the ground that would otherwise remain fallow for growing potatoes. This not only supplies a useful crop, but also helps to clean the ground. Trenching for this purpose can be done in spare moments throughout the winter. This saves a fine crop of weeds coming up in fallow ground during the coming season.

HAVE YOU

¶ *Increased by cuttings your rambler and pillar roses?*

¶ *Planted your St. Brigid anemones?*

¶ *Removed to a cool, airy greenhouse your cinerarias, cyclamen and primulas which have been growing in a frame during the summer?*

¶ *Planted in your rock garden such bulbs as the hoop-petticoat daffodil, glory of the snow (chionodoxa), grape hyacinths (muscari) and the spring snowflake (Leucojum vernum)?*

¶ *Repotted your greenhouse azaleas?*

¶ *Planted out into their permanent quarters your Canterbury bells and sweet williams?*

¶ *Inserted cuttings of your gooseberries, red and black currants, and layered your loganberries?*

¶ *Cleaned up, lightly forked over and mulched your rhubarb bed?*

¶ *Started root-pruning your fruit trees which make excessive wood growth and are unfruitful?*

Heath as an Edging.

FOR many years box has been used as an edging plant, especially by the pathside; in fact, it has been supreme. Now, however, some of the heaths are coming into fashion, and it is a fashion that will certainly increase. This practice of growing heaths as edging plants has many points in its favour. They are neat plants, they grow quickly, they flower profusely over a long period, and they are easily propagated. Erica carnea is excellent for this purpose, but the best of all is undoubtedly the heath that is called St. Keverne. Edgings already exist made out of it over a hundred yards in length, with every plant the same size and smothered with bloom throughout almost the entire summer. Any garden that is lime free can possess such edgings. All that is necessary is to buy a few plants from which to take cuttings, which are easily struck in sand under a bell glass or in a frame. When struck these should be planted fairly close together, about 4ins. to 6ins. apart. They can be clipped in the same way as box and so can be kept trim and neat. In fact, the St. Keverne heath is *the* edging plant. Why not try it?

Particulars of this month's Competition will be found on page 583.

PLANTS AT THEIR BEST IN AUTUMN

This is the fourth of a series of contributions to THE GARDEN *by the well known writer on horticulture, Mr. A. J. Macself. It is an enlargement of our Notes on "Worthy Plants" that have been such a popular feature.*

A Fine Veronica for Edging.

IN conjunction with the scarlet Salvia Harbinger, previously mentioned in these articles, I planted a front line of this charming veronica (V. Andersonii variegata), and throughout the summer the belt of elegant and pleasingly light foliage made a setting for the salvias which it would be difficult to surpass. It is now, however, that the value of this border plant is greatest; the plants have grown into a regular unbroken line of sturdy bushes, the older foliage taking on a darker but still pleasing green, with cream edges, the younger foliage being more white than coloured. Since October started, the plants have produced quite a show of their fluffy tassels of turquoise blue flowers, and although the precise artistic taste for colour harmony might raise objection to bringing such a shade of colour into contact with scarlet, the profusion of white-margined leaves and the space between the veronica flowers and the scarlet spikes of the salvias save the situation. At any rate, the plant itself is a treasure, and if it is used in the manner I used mine there is no difficulty in pinching off the buds should the colour-clashing idea disturb one's mind; while, if planted by itself, the turquoise blue is an extremely pretty colour.

My next move is to use this beautiful shrub for window boxes, a sheltered position on the south-western side of the house being quite suitable for its winter quarters.

VERONICA ANDERSONII VARIEGATA MAKES AN EFFECTIVE EDGING TO A NARROW BORDER.

A Desirable Flowering Shrub.

IF the colours of the hypericums were as varied as their forms and habits of growth, we should surely find a vast number of garden enthusiasts vying with each other to possess the most complete collection. Being a yellow-flowered genus, a few usually suffice for the requirements of most gardens, and the result is that some of the most charming species and varieties are but seldom seen. It is not often, for instance, that H. oblongifolium is met with, but it is one of the most desirable of flowering shrubs, and is particularly entrancing during the sombre days of late autumn. Never a canary had plumage of a brighter, purer yellow than the petals of this flower, and it is a flower of beautiful cupped form, as refined and chaste as the less easily grown Dendromecon rigidum, which everyone covets but only the comparative few can possess for any length of time. A great point about Hypericum oblongifolium is that yearling plants from cuttings will bloom freely on wiry stems of a foot long, and plants will gain in size year by year until they attain a height and diameter of 4ft. or 5ft., and will yield a great mass of bloom. When a plant exceeds convenient dimensions, all that is necessary is to cut it back and start afresh.

A Charming Variegated Heath.

A CHOICE little variation of E. vagans alba, flowering well on quite small young plants, E. v. Lyonnesse was one of the tit-bits of Maxwell and Beale's late autumn exhibits, and it is one of the ericas that all who are really interested in the finer points of variation and charm in the hardy heaths should secure. There is a loose, shaggy sort of appearance about both the growth and the flower heads that makes it totally different from the ordinary form, and the bells are slightly larger, globose, and apparently, if not actually, purer in their whiteness. This may in part be due to the loose formation of the inflorescence, and it is accentuated by the particularly bright colour of the protruding stamens. I am disposed to call that colour terra cotta, and, if contradicted, will say: Very well; let it be red ochre—and anyway, it is a pretty colour in these tiny pinheads, whatever it might be in a big splash. E. vagans Lyonesse might, for all I know at present, lose some of its distinctive character after several years' development, but if that should be the case it would be adequate reason for frequent propagation and replanting; it is worth all that to retain its best character.

An Elegant Grass Worth Growing.

AMONG the grass family, replete with plants of fairy-like elegance, few can excel Miscanthus zebrina—when it is happy; but truth to tell, it is far too often an unhappy plant, by reason of the prevalent, but erroneous, custom of planting it in swampy ground.

Years ago I followed the rule, and planted what was then invariably called Eulalia zebrina in positions where one's boots sunk into the saturated soil, or where the roots might, at any rate, get down below the water level, and, like my friends, I grieved over the lack of hardiness of this plant that had won my affections. I grew some in pots, and used to flood them incessantly; but, by some accident, a plant escaped the water pot sufficiently to let me into the secret that it is when dry that it will thrive contentedly and bring out its most conspicuous contrasts in green and cream. That season a few plants from pots were planted on a dry bank, and, after watering to give them a gradual change from their former state of incessant saturation, they were left to themselves, and in the course of a single season they made some grand specimens. Within the past week or two I have seen Miscanthus zebrina in several places, and the magnificence of the foliage and development of the feathery plumes has been in corresponding proportion to the dryness of their position, the best plant being in the centre of a raised bed the soil of which is upheld by a surrounding wall of flints.

Just another point about this unique rush; it pays to lift, divide and replant about every third year. Older plants become hollow centred, and seldom maintain symmetry. Treated thus, there is no need to doubt the hardiness of this very lovely grass.

Phlox "Border Gem."

THE name of this phlox has appeared in print a number of times since August, for it has been widely exhibited by its raisers, Messrs. E. F. Fairbairn and Sons. There is, however, more in this variety than the mere fact that Border Gem is a near approach to a blue border phlox; it is particularly commendable as a variety that may be had later in bloom than almost any other, especially if grown from spring-propagated cuttings or, alternatively, if established plants are allowed to grow until a foot high and are then cut down for encouragement of second growth. The whole structure of the plants —stem, foliage, truss and pip—is of unusual firmness and strength. The individual pips are as perfectly outlined, and are smooth. The truss is built on the whorled pyramid style. But that is not the sole point of importance, for it is this smoothness of pip and evenness of truss, combined with the thick substance of the petals, which result in a flower calculated to endure both drenching rain and autumn night mists with far greater impunity than the broad, loose, flat-headed trusses covered with large but irregularly waved or folded petals, such as are so prevalent among the Continentals. It would be quite possible, by adopting the spring propagation or the cutting back already referred to, to make plenty of the German phloxes bloom very late, but Border Gem would beat them because of the distinctive characteristics here mentioned.

A DESIGN FOR A SMALL GARDEN

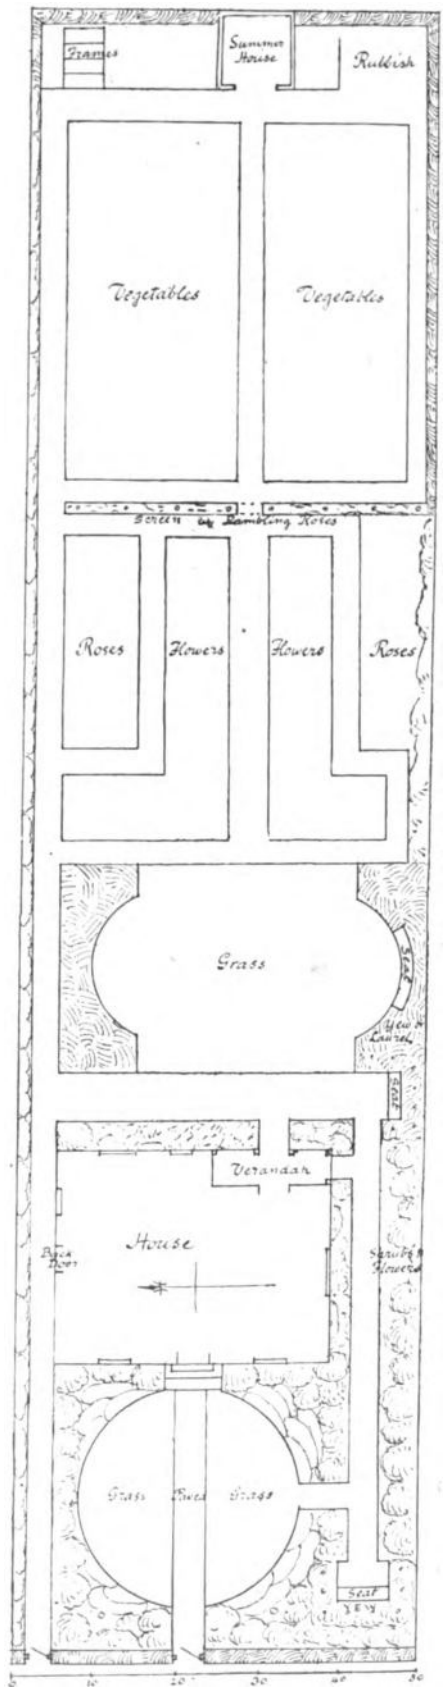
By GERTRUDE JEKYLL.

In this plan Miss Jekyll shows how attractive a long and narrow plot can be made with sufficient foresight. As this shape and size of plot is common, these suggestions are sure to prove invaluable to many of our readers.

THIS plan shows a site with a frontage of 50ft. to the road and a depth of 200ft. A paved path leads from the front gate to the house door through a circular grass plat. The tradesmens' entrance is on the north side; a narrow space on the left of it against the fence serves for the placing of such shrubs or flowering plants as can be kept within this small width. There are many pretty ivies that would serve, and the ever useful, but not very interesting privet, and a number of roses. This path continues right down as a service track to all the sections of the garden. For the main shrub planting there will be a good proportion of laurustinus, especially at or near the angles of the house. In any case it is best that the shrubs on this entrance side, at least, should be mostly evergreen, in order that the house should have a well clothed appearance in winter. Besides laurustinus, there are many other ornamental evergreens with fine leaves that remain attractive throughout the year, among them the smaller skimmias, St. John's Wort. Next to the road there will be a distinct hedge. Cupressus macrocarpa answers well for this, or green holly, or the always useful, but lately neglected laurel. The small circles are standard flowering trees, a pair of the beautiful early-flowering crab, Pyrus Malus floribunda. As the space is wider on the south side, there will be a way out from the grass plat, joining the path that leads past the house on the same side. It turns a little way towards the road, where there is space for a seat, comfortably screened by yews.

Next to the house on the garden side there will be small shrubs—lavender, rosemary, Olearia Gunnii, etc., with a white jasmine, and perhaps a wistaria on the veranda and a laurustinus at each end. This kind of permanent planting next to the house-foot, is much better than the rows of soft summer plants that are so often seen, and that are out of character with the solidity of the near structure. A wide path passes along this front, with a shaded seat, embowered by yews, at the southern end. Then comes a grass lawn. The partly circular shaping of this at the two ends, helps to counteract the feeling that the ground is one long strip. In sites of this kind the more they are cut across, in following sections, differently treated, the better. It is advisable to keep the lawn quite quiet by letting the planting at the two ends be of one kind of evergreen shrub only—yew, holly or laurel. There has been of late a prejudice against the use of laurel, quite unfair to this valuable shrub, for, if worthily treated, it is one of the best of evergreens.

The next division will be a wide, double flower border, L shaped, with beds of roses at the back; the appearance of this will be much enhanced by the quiet of the lawn. Seen from the house windows this flower garden will make a brilliant display, pleasantly framed by the quiet green of the lawn and its evergreens. This garden will end in a screen of rambling roses; the remainder of the ground forms convenient quarters for vegetables. It is hoped that there will be a good summer-house at the far end, for in addition to providing a desirable alternative to the rooms of a small house—not only for pleasant rest, but reading writing or study—it ends the long vista with something distinct and permanent; and if the path through the vegetables is bordered on each side with small fruit bushes, the eye need not be offended by patches of half-cleared cabbages or newly turned-up earth, or any other of the useful but unbeautiful aspects of the kitchen garden.



PLANTING HARDY CREEPERS AND CLIMBERS.

WHEN autumn closes in and falling leaves give evidence of the swift passing of many of our garden treasures which have kept us company these many months, we are reminded of duties that must presently be attended to. Among such is the planting of creeping and climbing plants if we would have our walls and pergolas and arches objects of beauty another season. It is the nurseryman's harvest. It is the gardener's opportunity. The business may be deferred for a time, but as a general rule, and also by consent of custom, autumn is looked upon as the best time of all for removing hardy climbers and replanting them in fresh quarters.

Most people, I think, in making a selection, have some idea of what is required. It may be that for long some object has been anything but attractive in the garden, and the time has arrived when a transformation may be brought about by planting something suitable and, at the same time, pleasing. Roses will possibly be needed. We may have our own ideas about them; some variety, seen perhaps in a neighbour's garden, has called forth our praise, and we have made a mental note that, whatever we order, we must have that particular variety. So many roses have been bought in this way.

We may have—like so many—a cold, bleak wall which has not received much attention hitherto. Why not plant ivies there? Somehow, when one mentions ivies, it does not always convey a sense of lightness and attractiveness, rather does one meet with folk who regard ivies as always being dull and sombre, but those good people have never made the acquaintance of the close-clinging gold and silver sorts that are charming nearly all the year round except for the few weeks when clipped of their foliage in spring, which enables them to appear in a brighter dress!

More attention is being given in these days to berry-bearing shrubs for training on walls, and one is not surprised to find that some of the pyracanthas, like the scarlet-fruited Lalandei, are making many adherents. It is not without value when the flowers appear, but its chief worth lies in its rich clusters of fruit closely studding the walls.

Whatever we plant, we should bear in mind that we are providing for future beauty in our garden, and therefore we shall see to it that the ground is well prepared by bringing in, if need be, suitable soil. Near to walls, as a rule, one finds builders' rubbish that is not helpful, to say the least, for the growth of climbers, however suitable it may be placed 2ft. or 3ft. below surface for drainage purposes. Nothing but the best and most suitable soil for our climbers should be found for them. It may involve trouble, and possibly expense, but we shall be more than compensated in the days to come by the freedom with which they grow and the pleasure they give us when the flowers and foliage and fruit appear. W. F.

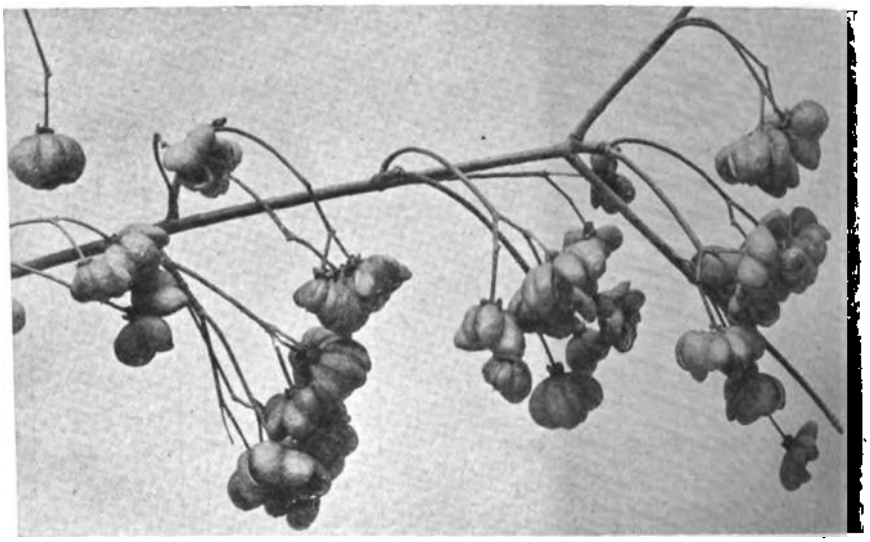
AUTUMN COLOUR IN THE GARDEN

IF the autumn tints of our landscape can not compare in splendour with those of some other countries, we have an immeasurable compensation in the fact that our climate and soil allow us to grow a range of exotic trees and shrubs so wide that even within the limits of a moderate sized garden one is able to enjoy many of the most gorgeous examples of autumn coloration which the world affords.

In my own woodland garden—and one gladly resorts to some limitation in attacking a subject so vast—autumn steals into the ebbing verdure of summer before August is half over with flushes of yellow and ivory among the bracken's green, with the glistening sealing-wax red of the wild arum's clubs, with clusters of fruits on Cotoneaster frigida and the even earlier red-berried elder. Then comes Berberis Thunbergii with its blaze of scarlet, reminding us once again not only of the great merit of this fine old shrub, but of its admirable punctiliousness. You may set the year's clock by B. Thunbergii, and no matter what the weather may have been, rely upon its accuracy in sounding, if not the first, the most poignant note of autumn's triumph over the verdure of summer.

Before the fire of Berberis Thunbergii has expired, the foliage of the yellow azalea has begun to assume the hues of its passing, its green giving way to bronze, the bronze to crimson and thence to scarlet or orange. Not only does this never too familiar shrub give us a generous range of wonderful and harmonious colours, but the leaves often remain in their full glory for several weeks, flaming in a splendour which few shrubs can equal and suffusing the misty sunlight of the woodland aisles with a warm and radiant glow.

Vaccinium corymbosum follows much the same process as the azalea, adding the beauty of its violet fruits to the tints of its ample foliage. In vivid red and yellow Enkianthus cernuus is not less striking, and Parrotia persica, in a neighbour's garden, is a sight for gods and men during that all too brief a period when it is mantled in crimson and gold. The sumachs bid their farewells to summer in magnificent shades of crimson, scarlet and bronze, and those who cannot grow Azalea pontica because of their limy soil, will find a selection from their genus (rhus) an admirable substitute.



THE BRIGHT ORANGE CRIMSON FRUITS OF OUR NATIVE SPINDLE, E. EUROPÆUS.

Down by the waterside where the irises are slashed with streaks of rusty yellow, Liquidambar styraciflua is refulgent with full-toned red, purple and orange. Here, too, is Spiræa arborea, its long and elegant fern-like leaves changing to a curious blend of orange and tawny red—in striking contrast to most of the other ash-leaved spiræas, which go off in pale yellow. Ribes americanum and R. aureum both press their claims to recognition among the best of autumn-colouring shrubs, and those who cannot accommodate the more robust of the vines and their allies, should not overlook Vitis vinifera var. purpurea. This, the claret vine, is a singularly charming subject for trellis or pergola, and if it is so planted that the evening sun gleams through its beautiful foliage, the deep purple of the leaves will become an intense blood-red, and thus it will remain from early September to the first frosts.

When the ramanas roses are chequered with yellowing leaves and apple-tinted fruits, little Rosa nitida will be aflame with vermilion and crimson. The soft emerald of R. alpina pales to primrose just in time to give a telling emphasis to the beauty of its scarlet hips, and the yellow of R. lucida is not less charming by contrast with the ruddy bark of its younger wood. But still more striking is the nasturtium yellow of Halesia diptera and the Judas-tree. Exochorda grandiflora and Forsythia suspensa have draped their slender branches with the same colour and the large, saddle-shaped leaves of the tulip tree will maintain their pale golden hue for many weeks. And here, against the shades is Hydrangea petiolaris, shrouding the trunk of a leaning alder with a pallor so blanched that its leaves only have to rattle down the woodland walk to play the part of those "ghosts from an enchanter fleeing," which we read of in the greatest poem on autumn leaves in the language.

In shrubs which are notable for both berry and leaf colour, the many newer barberries and their hybrids are, perhaps, supreme. But it will be much later before these come, and one looks to them to fan the embers of the season into that fierce glow with which they challenge the very gates of winter. To-day it is the cotoneasters which hold the field in these dual features. C. horizontalis, its broad planes 15ft. across, is laden with a scarlet crop of fruit, which will shortly yield place to the vinous purples of the dying leaf. Distinctly showy in berry alone are C. Dielsiana and C. Francheti, but the bronze and orange foliage and copious clusters in a glistening tomato-red of C. bullata, place this species in the very front rank where both fruit and leaf colour are concerned. C. adpressa must also have its meed of praise for its mellowing foliage and scarlet berries are in the most delicate accord. Nor can one overlook the peculiar beauty of our native spindle (Euonymus europæus), whose orange-coated seeds are canopied by an "aril" of coral. E. latifolius may run our spindle very close in ornamental value, its jewelled "ear-rings" being more than double the size and of a bright crimson and orange. But this does not fruit so generously as the native. Both of

BERBERIS THUNBERGII, ONE OF THE BEST OF THE AUTUMN COLOURING BARBERRIES.

Digitized by Google

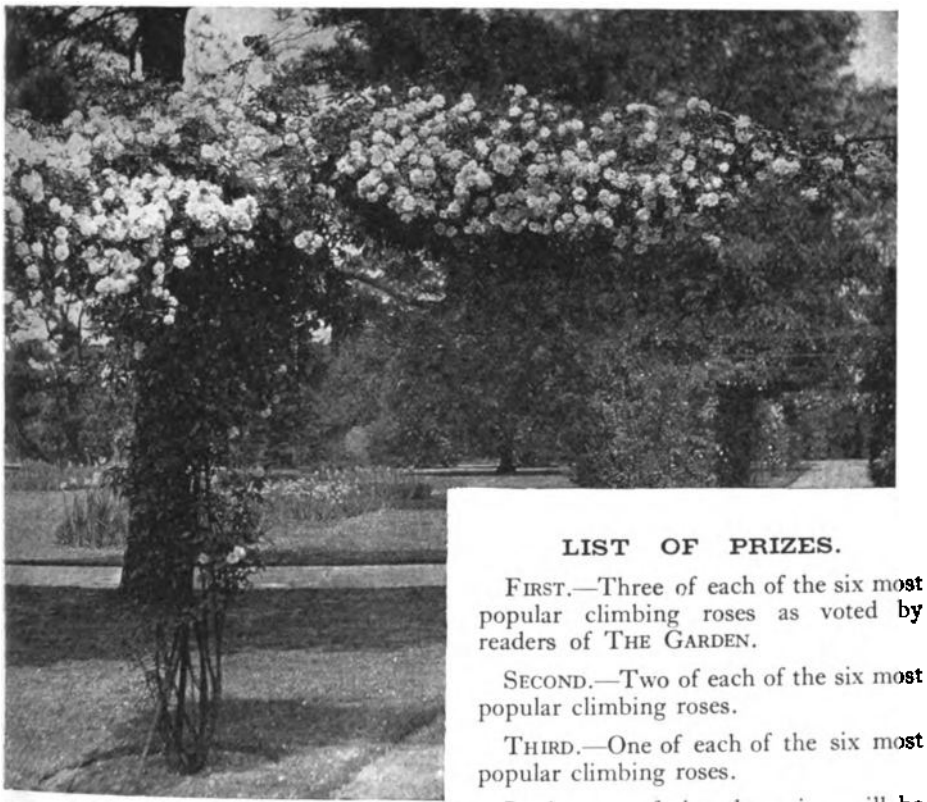
these, and I must include E. alatus, develop gorgeous leaf tints, their rich bronzy-reds being pervaded with stains of bright rose.

Though I have passed by the witch-hazels and maples, the smouldering fires of the beech and the incomparable gean, space in these notes must be found for a brief notice of a few of those herbaceous plants which have their place in autumn's pageant. Among these is the sensitive fern (Onoclea sensibilis), whose emerald fronds are now a clear, soft buff. Solomon's seal is never more handsome than it is to-day, when its pendants of jet swing in the radiance of its golden leaves. The brilliant tints of Geranium ibericum have a serious rival in the more vehement blood crimson of G. Loweii, as happy a woodlander as any Herb-Robert, and gleaming with a primrose light in shady places is the bold foliage of Funkias Sieboldii and Fortunei.

The noble leafage of Saxifraga peltata is among the first of herbaceous things to surrender, its big leaves passing into a tawny orange, and here where the willow gentians are still abloom, where the glossy green carpet of Polygonum vaccinifolium is being invaded by the "sere and yellow" before the last of its rosy-pink has left its upturned spikes, are the mellow browns of osmundas, the coppery hues of rodgersias and tall ranks of Lysimachia clethrioides in a bleached straw gold. Against the deep green of an ivied slope the tall sheaves of antholyza and montbretia, all stained and streaked with rust and yellow, are emphasising the inestimable value of a dark background where autumn colour is concerned. Kirengeshoma palmata asserts the same truth from a shadowy retreat where, with the crimson-dyed Galax aphylla for company, its big, vine-like leaves have at the first gentlest touch of frost surrendered their hearty olive green for a sapless ivory, wan and pale.

N. Wales. A. T. JOHNSON.

THE ROSE GARDEN



THIS MONTH'S COMPETITION

SO much interest is now being taken in climbing roses of all kinds that in this month's competition we are anxious to test the popularity of the various kinds by asking our readers to vote what, in their opinion, are the six most popular climbing roses. No matter to what class it belongs, a rose is eligible so long as it climbs. This should prove of interest to everybody, for opinions differ more regarding climbing roses than they do on bush roses. The use that the climbing rose is put to has now increased to a large extent, since they are planted in positions that before the war would have been considered impossible. In fact there is little doubt that the climbing rose has an immense future in front of it, since all gardeners are paying more attention to its importance. That being the case, we are sure that all readers, whether keen rosarians or not, will enter for this competition. The more that enter the more certain will the result be. Remember that it only lasts for two weeks, so be sure to fill in your coupons at once.

LIST OF PRIZES.

FIRST.—Three of each of the six most popular climbing roses as voted by readers of THE GARDEN.

SECOND.—Two of each of the six most popular climbing roses.

THIRD.—One of each of the six most popular climbing roses.

In the case of ties the prizes will be divided.

RULES.

1.—A list of your choice of the six most popular climbing roses to be sent in in order of preference on the coupon to be found on page iv of this week's issue of THE GARDEN. A coupon will also be found in next week's issue.

2.—No reader may win more than one prize, but they may send in any number of lists, provided that they are written on the special coupon to be found in this and the next issue.

3.—Coupons must reach this office not later than Tuesday, October 26th.

4.—Envelopes must be marked "Competition."

5.—The popular vote will be final and no correspondence will be entered into over this competition.

6.—The result will be announced in the issue of THE GARDEN, November 6th.

7.—The Editor's decision on all points is final.

ROSES FOR FENCES AND BARRIERS.

THE introduction, years ago, of Crimson Rambler and, later, of Dorothy Perkins, was a new departure in the rose world, inasmuch as it was found that these almost irrepressible climbers could be grown and bloomed with a certain amount of satisfaction in the very heart of a town. Though these two have long been superseded in many places, they still have a wide sale, and are grown for the purpose of quickly covering fences and acting as barriers. We have progressed a good deal since those days, and now have a wealth in varieties enough to satisfy the most fastidious, notwithstanding the fact that the season of flowering of the Wichuraiana is brief. Albéric Barbier, creamy white; Shower of Gold, bright golden yellow; American Pillar, pink; Excelsa, crimson scarlet; Romeo, deep red; and Hiawatha, single crimson, are among sorts that enjoy a wonderful popularity. Some of the old Ayrshire roses, such as Bennett's Seedling, semi-double white, and Dundee Rambler, make capital coverings wherever one desires cluster roses that will soon festoon trellis-work or drape a wall.

Beyond personal observation and my own experience, I have no information as to whether the sale of rambler roses is on the increase or not; but of recent years I have noticed that many have uprooted strong-growing sorts of the style of Dorothy Perkins in favour of some of the climbing hybrid teas, a new race, so to speak, that cannot fail to please when we remember their long season of flowering and splendid assortment, from General McArthur, Liberty, Richmond, Mme. Abel Chatenay, Ophelia and many others, that only a few years ago were known and grown as dwarfs.

It may be said of this new section that it has opened up a wide field and, instead of our walls and fences being covered with roses that will bring a glamour of colour for a few weeks and then cease to charm, we have an opportunity of planting sorts that will flower with the same continuity as we have been accustomed to have in their dwarf forms. I predict for these climbing hybrid teas a wide patronage as their usefulness becomes better known.

In the next few weeks many will be studying catalogues with a view to ordering roses for the covering of walls and pergolas and the hiding of fences and barriers, and, doubtless, some of the climbing forms of hybrid teas will appeal to those who hitherto may not have made their acquaintance.

The site for the roses should now be prepared for planting by deep digging and applying to the soil a good dressing of well rotted manure, or if the latter is not obtainable, Wakeley's Hop Manure, an excellent substitute, should be used. W. F.

THE BUSY MAN'S PAGE

Ten Perennials Which Look After Themselves.

ALL the perennials mentioned here are perfectly hardy, easy to grow, and can be planted within the next few weeks. When once established they need very little attention, and will bloom well year after year. They are not particular as to soil, provided the site is well prepared and the drainage is good.

ANEMONE JAPONICA QUEEN CHARLOTTE.—*A Japanese anemone with flowers of a delicate pink shade borne on stems 3ft. high. Plant in cool rich loam in semi-shade. In front of a shrubbery is an excellent site.*

GALEGA OFFICINALIS.—*This goat's rue produces small lilac pea-shaped blooms from July to August. It is tall-growing and should be given plenty of space in a corner of the mixed border.*

HELENIUM PUMILUM MAGNIFICUM.—*A dwarf sneeze-wort with large golden yellow flowers. It is suitable for the herbaceous border, grows to a height of 2¾ft. to 3ft., and blooms freely from July to September in any good garden soil. Staking is unnecessary.*

HEMEROCALLIS FLAVA MAJOR.—*A showy day lily with canary yellow blooms produced during June. It should be planted in bold clumps in a sunny position, or in beds alone.*

LUPINUS ARBOREUS.—*The tree lupin is most suited for a sheltered sunny position, where it forms a large bush. It bears yellow flowers from July to September.*

NEPETA MUSSINI.—*An attractive catmint with silvery grey foliage and violet blue flowers. It can be grown with the greatest of ease and blooms throughout the summer. It is suitable for edging a perennial border, or for clumps in the rock garden.*

PEONIES (DOUBLE CHINESE).—*Any of the well known varieties of this type of peony succeed in well dug and manured soil in a south-west or west aspect. Good varieties are Victor Hugo, carmine; M. Chas. Leveque, salmon pink; and Duchesse de Nemours, pure white.*

PAPAVER ORIENTALE.—*For producing a brilliant effect Oriental poppies are invaluable. A sunny position in a border or the front of a shrubbery suits them well.*

RUDBECKIA NEWMANII.—*A cone flower with large orange yellow blooms which have a conspicuous black centre. It flowers during late summer.*

THALICTRUM AQUILEGIFOLIUM PURPUREUM.—*A handsome meadow rue with flower-heads of rich mauve-purple produced in mid-summer.*

How to Ripen Hard Pears.

AN interesting way to hasten the ripening of hard pears is to pack them in a box of hay. Get a good-sized wooden box which is rather deep. Into the bottom of this spread a layer of hay about 6ins. in depth. Then arrange the pears singly with a fair amount of space in between. Add another layer of hay and then put in more pears. These should be covered with further hay and, if there is room in the box, a third batch of fruit can be set out. Finish with a good thick covering of hay and, on the top of this, place some boards of wood. Arrange the pieces of wood so that the whole of the hay is well covered, and then finish with a number of bricks or anything heavy. The idea is that the pears in the hay shall be subjected to a continuous pressure and, within reason, the heavier the weights the better. Now and again the pears should be examined and those that have become soft and sweet taken out. The length of time required depends upon the variety, but some kinds will be fit for eating in ten days. The best way is to treat small quantities of fruit in this way, taking them from the store as required.

Maidenhair Ferns.

AT this time of the year maidenhair ferns will often languish very badly indeed. Of course, the plants are entering on their resting stage, but most of the adiantums are of evergreen habit, and there is no reason why they should not keep up a good show of fronds even in the winter. Usually the cause of the dejected appearance of the ferns at this season is due to the fact they are overwatered. For the next two or three months maidenhair ferns will require very little water indeed, not more than is enough to keep the soil from getting absolutely dry. If there is any doubt about the drainage, do not hesitate to tip the plant from the pot, loosen the soil a little at the bottom, and then re-arrange the crocks. A friend of the writer, who always managed to keep half a dozen maidenhair ferns growing in a room in a state of great luxuriance all through the winter, attributed her success to castor oil! In the late fall of each year she poured just one teaspoonful of the oil on to the soil of each pot. Whether her success with the ferns was due to the castor oil or not, it was remarkable how well the plants carried their fronds in the somewhat unfavourable atmosphere of a living-room.

A HANDSOME MAIDENHAIR FERN IN MID-AUTUMN.

Hardy Plants for Indoor Blooming.

IN the late autumn, when clearing up and dividing plants in hardy flower borders, many things will be found suitable for potting up and relegating to a cold frame for a few months until they have become established, preparatory to bringing them under glass for early blooming. By introducing hardy plants into a greenhouse one is able to obtain quite a variety of blossoms, and if one is careful to arrange matters so that plants can be transferred to a slightly warmer temperature, the house can be kept gay for many weeks. In making a selection, only those clumps known to be strong should be chosen, and it is important that they should have a long period in a cold frame or outhouse under ashes away from light to enable roots to make progress before any attempt is made to introduce them to a higher temperature. Some of our most familiar garden flowering plants will serve our purpose if only we are prepared to give them a period in which root action can continue. One old border plant which readily responds to warmth and moisture is Dielytra spectabilis, whose pink racemes and glaucous foliage make it a handsome subject for the cool and moderately warm greenhouse. Deutzias, like gracilis and crenata, give a prodigality of white blossoms. Spiræas are attractive from the point of view of foliage and flowers, too, from the old form of S. japonica with its white spikes to the more modern America with soft lilac flowers or the deep pink of Queen Alexandra. Comparatively few look upon pyrethrums in the light of plants for potting, but, while nothing in the way of forcing [as it is generally understood should be attempted in their case, one may have them in bloom weeks before the clumps out of doors have shown signs of buds by growing them in a slightly warm temperature after they have been kept for a time in a cold frame to promote root growth. Few plants in our gardens serve us better when potted up than campanulas, and of these C. persicifolia in its various forms and C. pyramidalis are worthy of note. Mention is made of that showy biennial the Canterbury bell, that in the coolest house gives a wealth of blossoms in late spring if only plants are potted up in autumn. These are but a few of the plants to be found in many gardens which, if potted and prepared, will bring bloom and beauty in a greenhouse in the spring.

Mistakes are sometimes made in attempting to force them into bloom before root action has taken place. It is useless to try to do so, as results are never satisfactory. The longer they can be kept in pots in a cold frame away from light until growth appears the better, as then only a slightly warmer temperature is necessary to induce them to bloom. Express treatment in the matter of bringing on hardy plants mentioned, and such as these, is one that cannot be entertained, except, maybe, in the case of water-loving things like spiræas, and gradual progress will always be found to answer best.

LONG-FLOWERING PLANTS

Here are a few suggestions for plants that bloom over a long period. These are valuable when planning additions to the denizens of your rock garden.

WHILE I do not propose to confine myself to rock plants in these short notes of plants which have a particularly long flowering season, yet most of those mentioned are worthy of inclusion in our rock gardens. The greatest, and sometimes the only disadvantage of many of our most beautiful plants is that their period of flower is so soon past. What an inestimable advantage it is when we can combine beauty with a long flowering season!

One of the best plants that I know for the rock garden, or even the scree, is Erodium chamædryoides roseum, it commences to flower in the early days of May and now (September) its dainty, deep pink flowers are still freely dotting the dark green carpet of its foliage on inch-high stems. Perfectly happy in any well drained and sunny nook or cranny, it is one of the best tempered plants and should be included in every collection.

Several of the erodiums have a very long flowering period, and although they are not so tiny and compact as the above mentioned variety, are splendid plants for bold positions in the rock garden. I should chiefly mention E. guttatum, E. trichomanefolium, E. amanum and E. chrysanthum, the last named is especially valuable as the flower is a lovely sulphur yellow, associating beautifully with the handsome silver foliage.

Although scarcely a plant for the rockery, being better in the front of the border, its colour and long season render Geranium Endressii a very desirable plant; it really seems never to be out of flower and the masses of rosy pink blossoms are ever welcome. One of the most beautiful colour combinations I have seen is a group of this, planted together with Borago laxiflora, an invaluable member of the borage family, whose rather straggly and leafy habit almost spoil its individual beauties, but when associated with other suitable plants it shows to great advantage numberless hanging bells of dainty porcelain blue.

I am always trying to decide definitely whether I like or dislike the borages as a whole, for with certain notable exceptions they possess far too much leafage for the amount of flower produced; on the other hand, their blue's are incomparable and they are invaluable in the formation of colour schemes.

The violas give us several varieties of great merit, one worthy of particular mention being the pure white form of V. cornuta, which is far too seldom seen. The flowers are produced in great quantity for months on end and when it does commence to fade, if it be cut over, it will promptly oblige with a fresh crop of virginal daintiness. The purpurea form is also long flowering and valuable, although not so noticeable.

The Grecian violet (V. gracilis), is almost too well known to need description; sufficient to say that it is one of the most indispensable plants we have and always seems in flower.

A really dainty daisy, that blooms from spring to autumn without a break, is Erigeron mucronatus. It is an admirable subject for wall and pavement planting, thriving well in any poor soil and sunny position. The countless numbers of daisy flowers open pure white and fade to a deep pink, and the effect produced by these and all the intermediate shades in flower at once is truly handsome. The whole plant is not more than 6ins. to 9ins. high.

THE DAINTY DAISY-LIKE BLOOMS OF ERIGERON MUCRONATUS ARE PRODUCED FROM SPRING UNTIL THE AUTUMN.

VIOLA GRACILIS, THE GRECIAN VIOLET, IS SMOTHERED WITH FLOWERS FOR MANY WEEKS

Those to whom an undoubted magenta is not objectionable should certainly grow Oxalis floribunda. If given a sunny corner in the rock garden to itself, where it cannot clash with any pinks, reds, etc., it is a sight to behold. It flowers freely from June to October, its 6in. stems bearing quantities of wide open flowers, which, although magenta, are not unpleasantly so, there not being sufficient blue in the red to render it objectionable.

For a long flowering period at a time when there is but too little colour in the rock garden, Primula Juliana gloria stands alone. It gives us masses of deep crimson flowers, peeping from among its dark green primrose leaves, from November onwards. To me, a group of this glowing colour bravely defying the elements, is one of the winter joys which are, alas, so few. The wahlenbergias contribute a very dainty and long flowering plant in W. vincæflora, its fragile looking, widely opened bell flowers are wonderfully attractive in their delicate tint of porcelain blue.

Gazania montana, although not a rockery plant and certainly not quite hardy, except in the west and some favoured spots in the south (generally needing the protection of a cold frame), is an extremely showy plant, with its huge, creamy yellow flowers and the dark blotches at the base of the petals and is well worth a sheltered, sunbaked spot somewhere in the garden.

All of the foregoing, except perhaps the last mentioned, may, I think, be termed indispensable plants, which should be grown in all gardens where a late show of colour is required, and it is one of the charms of the well ordered rock garden that there is something to be seen almost all the year round.

W. INGWERSEN.

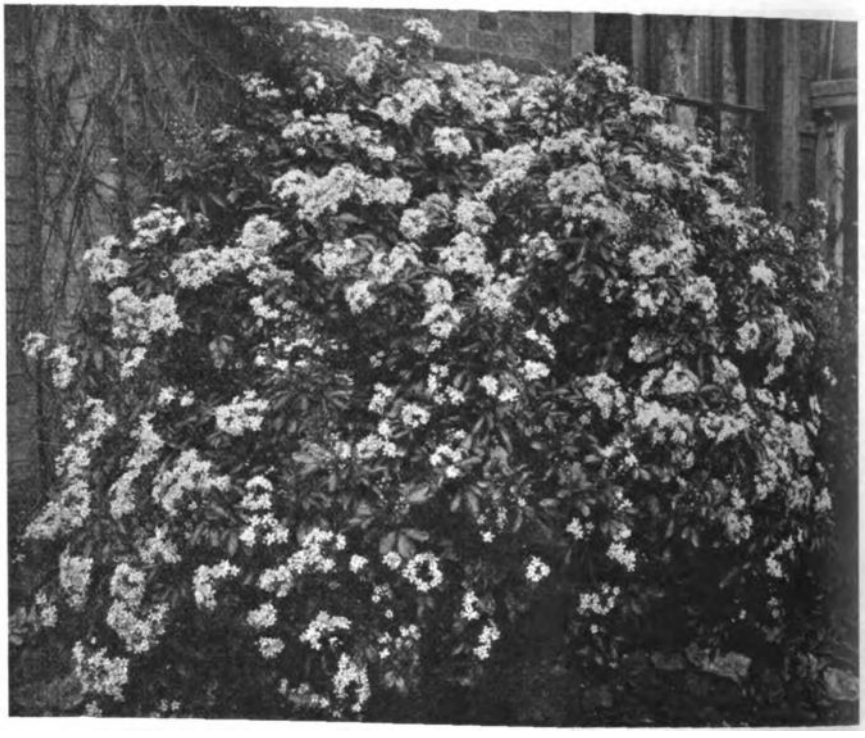
WHY NOT VARY YOUR SHRUBS?

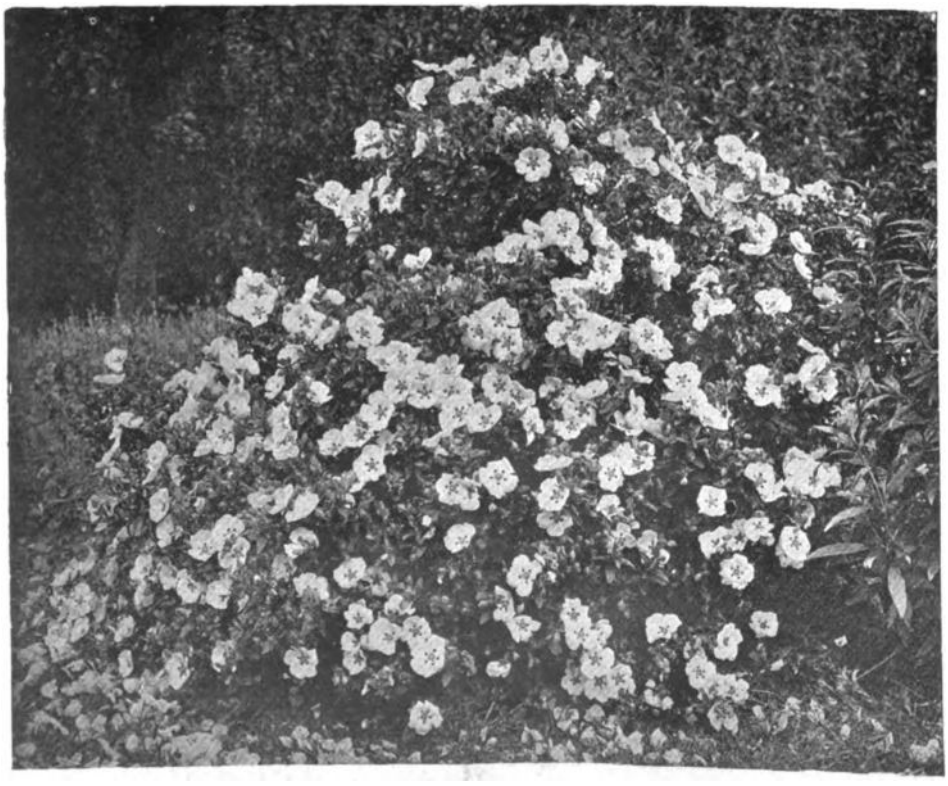
Whatever size your garden may be, it will be improved by planting at least one or two fine flowering shrubs. In only too many gardens aucubas and privet are still given preference. Remember that if a shrub bears magnificent flowers it does not mean that it is difficult to grow.

FROM the number of letters that are sent in to our Service Department from readers who want to know what shrubs to plant in their gardens, it is obvious that more and more amateurs realise that even the smallest garden can be improved by planting one or two fine flowering shrubs. In the old days there was a mistaken idea that flowering shrubs were useless in anything except a large garden, with the consequence that nothing was seen except aucubas or laurels, or privets or holly, with an occasional laurustinus or buddleia of poor quality to give variety. The truth is that these shrubs have certain qualities that make them useful as blinds or in odd corners where evergreens are invaluable, but so many choice shrubs are now common and cheap that the former should be sparingly grown. As decorative shrubs they are entirely out of date. Unfortunately, they are still only too common, especially in old-established gardens, where the gardener, whether amateur or professional, may be more interested in his herbaceous border or in his annuals or vegetables. If he only realised that a good shrub takes no longer to plant and requires little more attention than a privet, he would not hesitate a moment, but have them out and plant something better in their place.

Let us try to suggest a few shrubs or small trees that can be called utility plants and that are suitable for every garden. A small selection of the best is too long for one article, so this feature will continue for a week or two, and even then one or two of the bigger groups, like the berberis, will be left out for the moment.



CHOISYA TERNATA IS A MAGNIFICENT EVERGREEN SHRUB THAT LIKES A WALL AT ITS BACK.



CISTUS LORETI IS AT ONCE THE HARDIEST AND THE MOST FREE-FLOWERING OF ALL THE ROCK ROSES.

First we come to the almond. This is already one of the most popular of small trees in gardens of small area, but even then it should be more grown. There are few flowering trees that succeed so admirably in a smoky neighbourhood. They rarely miss blooming freely in March or early April, and they are admirable for growing as a standard in the middle of the front garden. No one can help loving the rosy hue of an almond tree in full bloom, even in the dullest of March days. Another shrub or small tree that is admirable for these reasons is Amelanchier canadensis or, to give it its popular name, the service berry. In this the flowers are pure white and are produced in great abundance. It is much more twiggy and a freer grower than the almond. The only fault to be found with it is the short life of the flowers; on the other hand, it is a fine foliage tree in autumn and the leaves turn either a rich red or a yellow according to the form.

Although buddleias are useful, yet they must be used with care, partly owing to the great size to which they grow, out of all proportion to what one unaccustomed to buddleias would imagine, and partly because some of the forms are poor in comparison to the size of the plant. There are two, however, which are worth growing, particularly in a corner where they can grow to some size. These are Buddleia variabilis var. Veitchiana, with long panicles of lilac flowers, and var. magnifica, rather deeper in tone and a later flowerer. Beautiful though the new Buddleia alternifolia is with its drooping branches laden with lilac flowers, yet it is inadvisable to grow it if you are confined for space, as it flowers

Digitized by Google

on the old wood, and so cannot be cut back like other buddleias.

Next we come to ceanothus, shrubs that are best seen against a wall. So good are they that it is surprising that more are not grown against the front of a house. The illustration shows a hybrid C. Veitchianus bowering a window, and a very charming sight it is. They are fast growers and most of them are quite hardy against a wall; also they are easily kept within bounds. C. Veitchianus has innumerable blobs of flowers of an excellent blue, while other good varieties are Gloire de Versailles, a rich blue and about the hardiest, and C. thyrsiflorus, a tall grower with paler blue flowers. An added attraction to these shrubs is that they flower from the end of June onwards, a time when flowering shrubs are not too common.

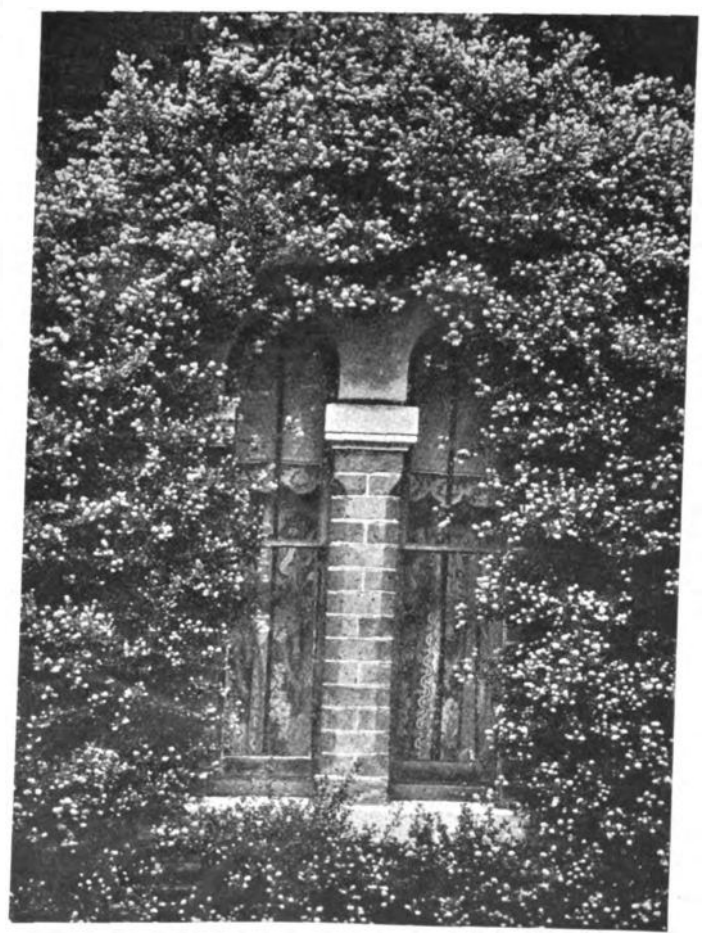
We must not forget Choisya ternata, which is one of the best of all flowering evergreen shrubs of lowish compact habit. Its habit makes it an excellent subject for growing under a window or in the corner of a house where its white flowers make a glorious show during April against the dark green leaves. It needs the shelter of a wall, but otherwise it likes a sunny position, while any good loam suits it. Although it is a Mexican shrub, yet it is quite hardy on a wall even in the north country.

For dry and sunny gardens there are few shrubs that give such a return as the cistus, for they will flourish in ground that is unsuitable for most plants. In June and July, given sun, they produce masses of their flat, platter-shaped flowers. The best varieties for ordinary purposes are C. Loreti, white flowers with a crimson blotch, and C. purpureus, of a purplish rose. Both are easily propagated by means of cuttings. If possible, two or three should be grown together in a clump, when the massed effect in full flower is wonderful. Two more useful shrubs for the front of the house are Cydonia japonica and its forms and Cydonia Maulei. The former grows to some size, while the flowers, which are produced on the old wood, vary in different tones of red. The better of the two is Cydonia Maulei, which should be far more often grown. It flowers profusely in late spring and early summer with colour that is usually like a brilliant blood-orange. It is dwarfer than the former, and so is most convenient, as it rarely exceeds 3ft. in height. It is really one of the most useful of all shrubs.

Above all, let us have more brooms. The beauty of a bush of a good variety in full bloom in May cannot be beaten. There are now varieties to suit every taste. If you want a small-growing bush, you cannot do better than grow C. kewensis with creamy white flowers, such as is seen in the illustration. If you want a different colour, try C. Dallimorei, of varying shades of pink and deep red. If you want a taller variety, try C. præcox with sulphur-yellow flowers, or the variety Moonlight of a soft white. They will grow in almost any soil and like sun. In fact, they are everybody's plants.

AMELANCHIER CANADENSIS IS A SHEET OF WHITE IN MID-APRIL.

CYTISUS KEWENSIS IS ONE OF THE BEST OF THE SMALL-GROWING BROOMS.



MANY A WINDOW COULD BE IMPROVED IF BOWERED IN CEANOTHUS VEITCHIANUS.

THE FRUIT AND KITCHEN GARDEN

Treatment of Ripe Grapes.

THE amateur grape grower is always anxious about his vines in spring, and while the berries are swelling during the summer months, but when the berries have coloured nicely he often relaxes that watchfulness that has been so beneficial in the past. This is a grave mistake, because well grown grapes are soon ruined after the ripening stage has been reached if there are errors of management. Ventilation is still an essential point. During a very bright day it is unwise to throw open all the ventilators wide. Very little air should be admitted on the side from which the wind comes, and only a small amount of ventilation is desirable at the front of the house. Air should be admitted in such quantity as to prevent any stagnant moisture resting on the berries. At night admit just enough air to prevent a stagnant chilly atmosphere. Fire heat at night, during the autumn months, is very beneficial used in moderation, and where fuel can be spared for the purpose. If there are pot plants in the vinery—and generally there are, then care must be taken to prevent any undue amount of water being spilled on stage or floor; furthermore, the necessary watering should be done early in the day. Watch practically every berry in every bunch, especially the berries near the centre of the bunch, and if one is found decaying, remove it carefully at once or it will cause the loss of many berries and probably bunches too. Keep the border surface soil dry, but do not disturb it or the dust will settle on the berries and spoil their appearance.

Thinning and Pruning Bush Fruits.

ALL bush fruit trees, if healthy and growing in a good soil, soon become a tangled mass of shoots if they are neglected as regards due thinning-out and pruning of branches. Then the resultant fruits are small and of poor quality. Also, we find that badly pruned bushes do not yield the maximum crop even in a year when everything is favourable to a high yield. From a long experience I find that autumn pruning has the best effect on the bushes, that the buds left are stronger, and the crop a week or so earlier than follows when spring pruning is done. Especially is this the case where gooseberries are dealt with. Before you put knife to branch take due note of the form of the bush; generally, you should prune so that the centre of the specimen is more open than any other part, as, naturally, the centre becomes choked with young wood first. Some gooseberries are pendulous-growing, others have the more upright habit. A pendulous-growing one should be pruned to an upper bud, shown at *a*; to counter the natural habit a little, as shown at *b*. To form spurs prune as shown at *c*, and to build up single and double cordons prune as shown at *d*, *d*.

In the case of white and red currants the leading shoot of a big branch is pruned as shown at *e*, and the spurs on the lower part as shown at *f*, *f*, *f*, *f*. Black currants are thinned out rather than pruned. The older branches, *g*, *g*, are cut out severely; the young ones, *h*, *h*, *h*, *h*, are retained. Take care of basal, pink-coloured buds, *i*, *i*, as these make fine young shoots in due course.

The Final Earthing-up of Celery.

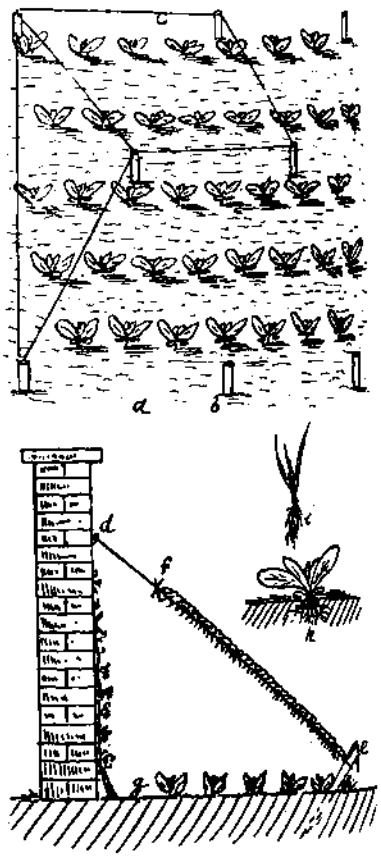
IF water can reach the roots of the plants in sufficient quantity, they will continue to grow till almost Christmastime. It is unwise to defer the final earthing-up too long, however. On the first fine day, now, place the final layer of soil to the plants pressing the loam very firmly round the plants and taking care that none of it falls into the centre of a plant, as it might cause early decay. The plants need moisture at the roots, but not round the stalks, so, to prevent rain entering there, make the sides of the ridges, especially near the tops, smooth, to cast off rainwater.

Early Broad Beans.

BROAD beans are a particularly fine dish early in the year and those who love them must not overlook the fact that earliest crops are obtained from sowings made soon after reading this. The old Mazagan was often recommended for this, but the Long-pods are equally hardy and, indeed, almost any variety will do. Autumn sowings, however, are not successful where the soil is heavy, cold and continuously sodden all winter; in light porous land, in medium warm loams, in stiff, well drained and sunny plots, they will succeed well. The ground should first of all be dug—the deeper the better—and at the same time a liberal but not excessive supply of manure may be incorporated in it; farmyard manure is best, but a semi-artificial mixture, like fibro-manure or hop manure, will serve. Plant the seeds 2ins. deep, 6ins. apart in double rows 6ins. apart, with 2ft. between each pair of rows. Shelter from cold prevailing winter winds is desirable, as such blight the foliage badly after a mild growing spell; if the spot is an open one, sow in the bottom of a trench or shelter the seedlings later with little spruce or evergreen twigs or, as we have often done, by a board erected alongside on edge.

Cauliflowers and Onions.

THE good gardener looks ahead and makes preparations accordingly. For example, he plants several varieties of broccoli so that heads, or curds, will be available from Michaelmas to early June. An early medium or late sort, only, would not serve his purpose. Having provided for a supply of broccoli to the month of June, he wishes to secure an early crop of cauliflowers to continue the supply through the summer until Michaelmas again. To this end he must make some



provision for the protection of young cauliflower plants from frosts and excessive moisture, especially in the northern counties, where I have, personally, had hard fights against severe weather, with regard to my cauliflowers. Of course, cold frames are ideal structures in which to winter the plants if they can be spared for the purpose. But in these days of shortage of fuel and the high cost of firing, many kinds of pot plants are wintered in the cold frames, being covered, in due course, with mats and straw. So the amateur must try some other kind of protection. Against excessive moisture in the soil, one can build up beds and, to a great extent, avoid it. Against severe frosts we can use simple means, such as the two illustrated. Among the plants *a*, stakes are driven into the ground a few feet apart as shown at *b*. Laths, or even strong string, *c*, should be fastened to the tops of the stakes to bear up mats, then dry litter if need be. Where there are low walls available, the young plants —also lettuces—may be planted in a nursery bed, as shown in the sketch. By fixing wires, as shown at *d* and *e*, mats, *f*, can be readily placed on or taken off in frosty weather. The plants are surface-rooting, but it is advisable to keep them at least 18ins. away from the stems of the fruit trees or 2ft. from the foot of the wall. By using a dibber the work of transplanting can be done more quickly but not as well as if a hand trowel be used. The roots should be spread out as shown at *h*. In the case of onions the same care is needed; but as the plants are to remain permanently, till maturity, in the bed, the soil should be deeply dug and enriched with manure first. The roots are very important and should be lifted out of the soil, not pulled. At *i*, the roots are shown intact. Allow a distance of 1ft. between the rows and 7ins. from plant to plant in the rows. Water thoroughly after planting, then keep the surface soil loose between the rows by using the Dutch hoe.

Digitized by Google

Preparing Frames for Winter Vegetables.

DURING the winter months the garden frame should never be empty. As a rule it is required for pot or border plants and cannot be spared for vegetables and salads. But there are roughly constructed frames in most gardens and such are suitable for the protection of young vegetables from October to early March, and then for several weeks more in the case of seedling vegetables raised in spring. There are positions in which beds cannot be constructed, there soil must be placed in boxes, but for such plants as cauliflowers the boxes should be at least 7ins. deep and filled to the top with good loam and some rotted manure in the bottom. In country districts and where there is a suitable frame ground, an old spent hot-bed with the frame on it and soil 1ft. deep inside, will prove very useful indeed. The soil, if good and quite sweet, free from insects and fungus, should be placed in the frame now, even if it will not be required for use until after Christmas, as it will not be exposed to rain and probably snow. The glass lights can be raised to admit air to the soil. If the insides of frames are to be painted, now is a good time to do the work, or to whitewash them as the case may be. As the bulk of soil in frames is not great, carefully examine it and be sure that it is free from wireworms.

Cabbages: Old and Young Plants.

IN normal seasons experienced growers do away with the old stumps at the earliest opportunity because they know that if left in the soil they will unduly rob it of valuable nutriment. The present season has been a very dry one in certain counties, and when rains come and start new life in the old stumps, the latter may, by some, be kept to bear sprouts. Do not rely upon them. However promising they may be, discard all old stumps, their retention would be a big mistake. Now with regard to the young plants. Winter is before them, it may be a mild one or very severe. We do not know, if we did we should prepare the soil to suit them; but, being ignorant, we must make the soil moderately rich and, if light in nature, very firm while it is in a dry state. The object is to grow quite sturdy plants that will withstand severe frosts without any serious damage. When the month of February comes we can feed the plants if they require nourishment—just force on the growth with the aid of artificial manures when the weather is mild enough, as from the latter part of March they should be fit to cut and the gentle forcing will result in tender hearts, as there should not be any frost severe enough to do harm. There will, probably, be six weeks of open weather from this date and, weekly, when the soil is dry enough, it should be hoed whether weeds appear or not, as this stirring of the soil tends to good health of all the plants. GEO. GARNER.

HINTS WORTH REMEMBERING

This is the fourth instalment of Hints that have been received from our readers in response to our request. There seems little doubt, judging from the numbers that have reached us, that this will prove a most useful feature of THE GARDEN *in future. We hope, therefore, that all our readers will assist to make this page as valuable as possible by sending in their Hints, the result of personal observation and trial, and so help the gardening public in general. Hints which will be specially considered as worthy of a prize will be those that are seasonable as well as interesting and apply particularly to duties that can be carried out in the garden at the present time.*

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Each must be sent in on a separate sheet and must not be more than 300 words in length.

THE HALF-GUINEA HINT

Protection Against Rabbits.

It is not widely known that fox oil is a sure protection against damage by rabbits in the garden. This rather evil-smelling oil is dissolved in a lathery solution of soft soap, until a liquid the colour of weak coffee is obtained, which liquid may then be sprayed on the plants attacked. It is not wise to use the solution on vegetables owing to the horrible taste of the fox oils. In badly infested areas it is a good plan to run all round the garden string soaked in the pure oil. Rabbits detest the smell, and will never pass such a barrage. Fox oil is known also as animal oil, bone oil, hartshorn dregs and Dippell's oil, and is frequently used by farmers to protect fields of young turnips and mangolds from wild rabbits.—E. D. S.

A Quick Way of Striking Polyantha and Rambler Roses.

Take short leafy cuttings, about 6ins. long, and lay in a box of damp moss an inch deep, pressed fairly firm at the bottom, with the cuttings lying on a pillow at one end with their lower half covered with more moss. Cover with a sheet of glass and put in a hot moist heat—as in a cucumber house. Shade from very bright sun and keep damp. They will root into the moss in about a month or six weeks.—R. D.

On Tying Celery.

Take the garden line, unwind it the length of the trench, twist it once round the top of each plant as one moves along the row, sticking the other peg in the ground at the opposite end of the trench; this will enable the worker to have both hands free when tying with raffia or twine. Remove the line when task is completed.—A. D. T.

Layering Rambler Roses.

The usual plan is to layer a strong shoot of the current season's growth around the parent plant, but by sinking a large pot, filled with sandy soil, in the ground and pegging down the cut portion made in forming the tongue, as near the centre of the pot as possible, the greatest measure of success is assured. All the roots may thus be preserved with ordinary care in removing the plants from the pots for transference to permanent positions. In the ordinary way there is the risk of damaging the roots when lifting them, and much of the soil is displaced from among them in the process. Treated as advised, well established specimens are secured in the shortest possible time.—J. C. C.

A Gooseberry Hedge.

The idea of making use of gooseberry plants as a dividing hedge, or edging for paths, is worth consideration at this time of the year. Prepare the cuttings in the usual way, but only leave two buds on opposite sides of the stem and close together. Insert these cuttings in the desired position about 9ins. apart, so that shoots produced from the buds will all lie in the same plane, *i.e.*, along a line joining the cuttings. As will be seen, as these shoots grow they can be interlaced and made to support each other. In the course of two seasons quite a good network is formed, and if the laterals are summer-pruned and then cut back in the winter, good crops are obtained which can be gathered with very little difficulty. The pruning is also quite straight-forward.—H. B.

For Killing Bindweed and Other Hard-Growing Plants.

Tie one end of a piece of thick wool round the bottom of the stem, the other place in a small bottle of turps which has been put in the ground near the plant. In a short time the plant will die off. In this way the writer has destroyed a bed of horse-radish.—M. E. T.

Furnishing a Round Bed.

Three years ago, in a round bed, I planted twenty-five tulip bulbs—Mrs. Moon—and, as a carpet, yellow polyanthus of Dobbie's best strain, and round the edge Sweet Peas Picture, John Ingram, Hawlmark Pink and Asta Ohn. As soon as the polyanthus have done flowering, I divide and replant them, after stirring up the soil and adding burnt earth. The tulips ripen off naturally and the polyanthus develop into fine plants for next season. When tulips have done blossoming, support sweet peas with good sticks, as up to this time small twiggy sticks have been sufficient. By the second week in June sweet peas begin to bloom and continue until the end of September, provided seed-pods are picked off, a feast of colour and scent. At the end of September I tidy up the bed and sow sweet peas for next year.

Last spring I had over 200 tulip blooms on the bulbs planted three years ago. This I attribute to the bulbs not having been lifted during that time and ripening off naturally. —M. K.

A Use for Old Rubber Tyres.

The prevalent winds of October and November often give gardeners much trouble in securing trees, bushes and sometimes branches. In place of the ordinary sacking to place round the trunk or stems of anything needing attention, I find a very valuable substitute in the use of discarded rubber tubes from car tyres. This, when cut into whatever length or width is required, and used instead of sacking, is preferable on account of its elasticity in giving to the swelling growth of whatever it is used for. Thus is a waste material made a valuable aid to a gardener's difficulties.—V. H. L.

How to Keep Plant Labels Readable.

Planting time is close upon us, and it is now that we should get our markers ready. In my early gardening days I was often stumped when trying to identify a plant that had died down, through the name on the marker being illegible.

An old hand gave me this tip: when using a marker always print the name on paint that is not dry. I found that no weather or soiling affects it; for, however dirty it is, a wipe brings the name up clear. I have dug up markers which were rotted to a shell on which the name was quite plainly marked.

When I intended planting and used painted markers, I used to take some thin white paint and, putting a little on a piece of rag, smear the face of the markers, rubbing the paint flat with the rag. These keep damp for quite a while and, when written on and stuck by a plant, dry as if varnished.—N. D.

SWEET PEAS FOR THE COLD GREENHOUSE

EARLY flowers of any species are always attractive, and sweet peas are no exception. Although sweet peas are first and foremost a subject for the open garden, no amateur growers who possess a cold greenhouse not lower than 5ft. at the eaves, will begrudge space given up to a few sweet peas. Even a dozen plants will produce a gratifying quantity of blooms well before the outdoor crop is ready and just when other flowers are scarce. The wonderful blooms seen at the Chelsea and other early shows of recent years are all from cold houses. They have been grown on the "cordon" or exhibition system, of course, but anyone who has seen them cannot have failed to notice their beautifully "clean" appearance.

System of Culture.

Unless the plants are grown on the "cordon" or single-stem system, indoor culture varies very little from ordinary outdoor culture. The seeds should be sown in pots or boxes in a cold frame in September or early October, plunging the pots to their rims in ashes, peat or soil to conserve moisture and to keep the roots from being cut by frosts. As soon as germination has taken place, remove the glass frame-lights entirely, giving the seedlings all the light and air possible, keeping them hardy and sturdy until it is time to move them indoors. Due precautions should, of course, be taken against slugs, mice and birds.

Wherever practicable, I advise planting the sweet peas out in the soil of the greenhouse rather than in large pots or boxes. It is not necessary to make any very elaborate preparation, or where space is limited, to have the rows farther apart than 2½ft. to 3ft. Just dig out a trench, or trenches, 2ft. wide and 18ins. to 20ins. deep, breaking up the bottom roughly to allow for efficient drainage. When digging, well mix in a good dressing of decayed animal manure in the lower 12ins., and if bone meal or wood ashes (or both) are available, they may be incorporated in both bottom and top layers with advantage. Should the soil of the greenhouse be suspected of sourness or if it is very poor, it is advisable to remove it, or at least the top 12ins., and replace with fresh soil from the garden. This will also provide an excellent opportunity for utilising such suitable material as the remains of an old hot bed, old potting soil, decayed leaf mould or anything of a like nature. Trenching may take place any time before Christmas, the earlier the better, and as a firm soil is essential, it should be trodden down as it is prepared.

Treatment of Seedlings.

In mid-January, bring in the plants from the cold frame and let them remain ten days or a fortnight in the greenhouse before transplanting. Water the trenches several days before planting out the sweet peas, making it fairly moist all through, but not "stodgy." Transplant the seedlings firmly 6ins. apart, and do not water too freely until strong growth commences. Support the young plants immediately with short twigs. Plenty of fresh air at all stages of their progress is an important point and no attempt should be made to force them by artificial heating. A fairly even temperature should be one's aim and careful manipulation of the ventilators will ensure this.

As soon as the plants are large enough, some kind of permanent support must be given them. While sticks will answer the purpose, wide mesh cord netting is neater and just as efficient. Fairly frequent watering will be found necessary, and when the first flowers open, a top-dressing or mulch of loose horse litter or spent hops applied around the base of the plants, and a periodical feeding with liquid animal manure and soot water will greatly assist them. Avoid overfeeding, particularly in the early stages.

After-care of Plants.

The only pest likely to be a nuisance is aphis and immediately these are noticed, it is best to spray the plants with a good insecticide, such as Abol, syringing them the next day with pure soft water to clean the foliage. As the season advances, mildew may possibly affect them, but this can be checked by spraying infected plants with a liver of sulphur solution in the proportions of ½oz. to the gallon of water. If the weather sets in hot and dry in the late spring and early summer, the power of the sun may be lessened by spraying whitening on to the glass.

Often, trenches in the soil of the cold house are quite out of the question, then one must fall back on large pots or boxes, using as a rooting medium good fibrous loam enriched with bone meal and wood ashes. A space should be left at the tops of pots or boxes for top dressing later, and both watering and feeding will, of course, be comparatively frequent. This method has one distinct advantage, which is that the sweet peas can be quickly removed to make room for a following crop as soon as their period of usefulness is over. If trained in a neat clump, they can even be taken temporarily into the house to beautify a corner of the hall or other position on special occasions.

Varieties to Choose.

Some varieties (or perhaps I should have written, some colours), are much more suitable for the greenhouse than others, and I would particularly recommend any of the lavenders, all orange shades, all whites, creams, cream-pinks, salmon cream-pinks, salmons, orange-pinks, pinks, blushes and any others which have orange or salmon in their colouring. The orange shades are especially beautiful under glass.

The cultural treatment I have outlined refers to the ordinary summer-flowering type of sweet peas, not the early or winter-flowering class. The latter are very precocious and will flower three months after sowing, given suitable conditions. They strongly resent transplanting, therefore it is advisable to sow them right away in large pots in a cold frame, moving the pots to their flowering quarters in November. Failing this, they should be sown singly in smaller pots and the ball of soil left undisturbed when moving them to their prepared trenches indoors. This early flowering type has not the same tendency to produce basal side shoots as the later, or ordinary type and the young plants should not be "pinched" for the original seed growth grows away strongly with very few laterals. Excellent varieties in a great many shades which produce large, frilly flowers on long stems, equalling most of the better later-flowering kinds, are now obtainable. It is perhaps advisable to point out, however, that this early-flowering type, although quite suitable in some climates out of doors, is of little use when given open-air treatment here, in England.

C. H. A. S.

WHAT OUR READERS SAY

GENTIANA SINO-ORNATA.

SIR,—The difficulties which for a time threatened the successful culture of this invaluable autumn-flowering gentian seem to have finally evaporated into the air, and wherever one goes one is confronted with thriving colonies of healthy-looking plants—of course, I refer to comparatively lime-free situations, for it is essentially a lime-hater, as are almost all of the ornata group.

Its requirements, so far as I am concerned, are a fairly rich soil—equal parts of peat or leaf-mould, and a good fibrous loam, with a dash of silver sand; planted in this and given full sun, it asks for nothing more, but just goes ahead.

If the plants are well top-dressed and filled up with a rather sandy mixture in the autumn, every shoot will root down, and in the spring each clump may be divided into many strong young plants.

My chief anxiety at present is to make G. Farreri as happy as G. sino-ornata; so far, it has not responded satisfactorily to any of my treatment. I grow it, certainly, and with a fair amount of success, but it is not really at home. In some gardens I know it thrives, and I should be much interested to hear other readers' experiences with this plant.

I certainly agree with the remarks made by "A. G. W." on page 543 of THE GARDEN with reference to G. Purdomi. I feel sure that it is one of the gentians of the future; the rather miserable plants we have so far seen are no guide to the beauties which this species can reveal.

A really well grown and flowered specimen is a sight well worth seeing, especially if it is a good form—for that there are forms *and* forms of many of the gentian species is an indisputable fact. I know of three distinct forms of G. sino-ornata, including a very early flowering one, which is rather valuable as it may be possible to procure good crops of seed, which is not easy with the later flowering forms. But to return to G. Purdomi. The colour is really good, a deep violet purple, and it is of good habit, showing its flowers well, seven or eight upturned blooms along a trailing stem. A good plant may have as many as a dozen stems, and I think that a mass of this plant would be rather a wonderful sight.—WILL INGWERSEN, *Sussex*.

"THE PROTECTION OF WILD FLOWERS."

SIR,—May I comment briefly on one or two points raised by your correspondent, Mr. H. Stuart Thompson, on the above subject.

He deprecates the formation of yet another society and predicts its probable failure, if formed. I sympathise very largely with his point of view. If the existing societies in the course of their campaigns displayed greater activity in restoring the beauties of the countryside, rather than the more negative attitude of proffering advice and exhortation—too frequently ignored—to all and every not to deface it, I should agree *in toto*. (Naturally, I make an exception in the case of societies interesting themselves in nature reserves.) Many of these societies have been conducting the educational campaigns to which your correspondent so properly refers, for months and even for years past. And, so far as I can see, the only apparent result is that in the neighbourhood of the towns and cities the denudation of hedgerows and woodlands increases in arithmetical progression.

The "encouragement of beautiful things" hardly finds expression in the bungaloth- some structures that like poisonous fungi,

Digitized by Google

are springing up everywhere along the new roads almost in a night, and are making blot after blot upon the landscape!

Enough of that. As to the Bill. The intelligent anticipation of the *Westminster Gazette* on August 16th seems a trifle premature, as, so far, I have not yet seen the Bill in draft form, and do not yet know, in fact, whether the Royal Horticultural Society has yet decided that legislation comes into the realms of practical politics.

As for "finding another job" for the hawkers who peddle uprooted wild flowers, I frankly confess that I have not made personal investigation and enquiry into the normal avocations of these people, but, when you see them in the streets, the great majority appear to be of the travelling gipsy type and the unemployables.

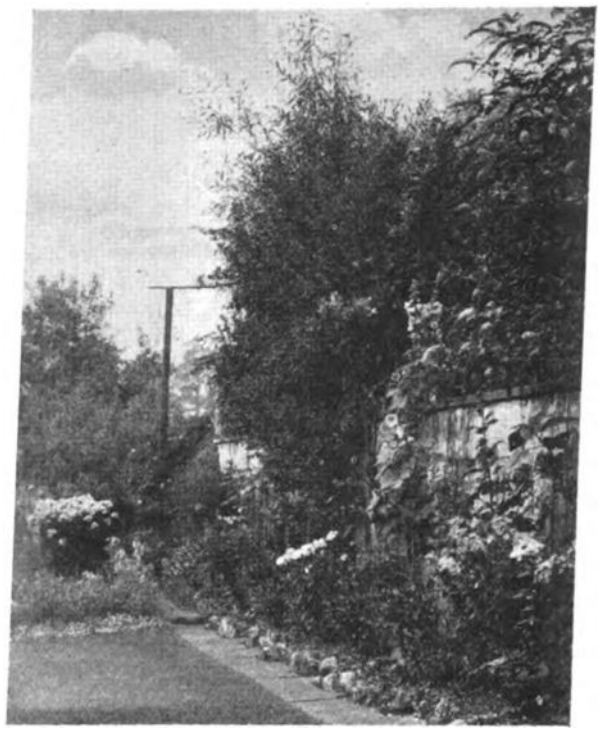
The last point, *viz.*, that raised by Mr. W. Howell, would defeat its own object. Every schoolboy is by instinct a collector — it may be of postage stamps, of conkers, autographs or what not—excite his interest, and, the collector of a rarity is a natural *sequitur*.

Again, the dividing line between the orthodox collector for the herbarium and the over-enthusiastic amateur inevitably causes the many sins, often the fruit of ignorance, committed by the latter, to be visited upon the former.—CUTHBERT JAMES.

A READER'S BACK GARDEN IN A SUBURB.

SIR,—I am sending you two photographs of my garden which is situated in a suburb of a large town and at the back of a row of four-storey houses, which effectually cuts off the sun from half of it. The portion shown is about a third of the whole length and as it is the end farthest from the house, it gets a fair amount of sunshine, except in the depth of winter. The rose on the tall post on the left of the first illustration (that showing the garden door), is Mrs. Flight; next it is a very good specimen of Albéric Barbier and farther along are Garland, Mme. Alfred Carrière and American Pillar. This border is planted with mixed perennials, including Oriental poppies in variety, delphiniums, phloxes, Aster Amellus, montbretias, geums and tall campanulas. White foxgloves make an effective show at the back in early summer and sunflowers later. The edging is of London pride. The bed at the end of the lawn is planted with mixed antirrhinums, edged with Alyssum Little Dorrit. The second illustration shows the other side of the same garden. The border here does less satisfactorily than its opposite neighbour, but phloxes do fairly well. The irregular stone edging was originally planted with mossy saxifrages, but they were a failure and did not bloom, so last autumn they were replaced by the commonplace but good-natured London pride. The poles and cross-piece at the end of the border were completely covered by two Minnehaha roses, but one died about two years ago and its successor has not yet made much growth. A nice specimen of Cistus ladaniferus is just visible at the end of the garden beyond the white phlox, and Clematis orientalis partly veils the wall. I may add the soil is very light, shallow and poor.

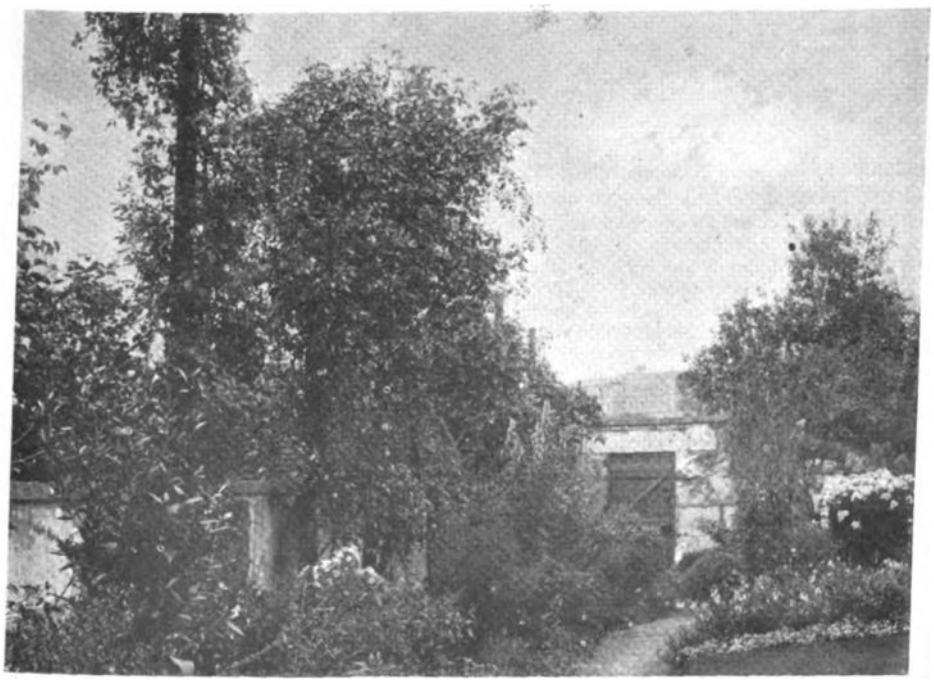
In my opinion the idea of illustrating your readers' gardens is an excellent one and to see what one's fellow amateurs are doing is both interesting and instructive.—H., *Bath*.



BY SKILFUL PLANNING AND PLANTING THE EFFECT OF LENGTH CAN BE OBTAINED IN EVEN A SMALL GARDEN.

PLANT COLLECTING.

SIR,—With reference to the above, and Mr. F. Runge asking for advice on the same. The following is the method we adopted last year when collecting native plants in Canada, to be sent home here and with which we have been most successful. Each plant we wrapped in sphagnum moss, the latter having first been soaked in water, then squeezed as dry as possible with the hand, after which it was carefully wrapped in greaseproof paper and tied. All plants were then packed tight in large tins, in which we made small holes, and sent home the same day as collected by the Canadian National Express. If dormant, or partly so, roots or bulbs were collected, we packed these in dry leaf-soil only. We collected from June until October.—R. MOORE, *Thorpe Hall*.



AN ATTRACTIVE MIXED BORDER WITH A BACKGROUND OF CLIMBING ROSES IN A SMALL SUBURBAN GARDEN

VIBURNUM RHYTIDOPHYLLUM.

SIR,—I quite agree with Mr. Briscoe that the above is a disappointing shrub. We have grown it here in several sheltered sites, and only after six years has it fruited at all, and then only once.

We have not grown it near V. lanatum, and is it worth the trouble with so many other handsome berried shrubs to choose from? It is certainly attractive swaying in the wind, when the foliage will show its silvery reverse, but in a very windy place this viburnum will not grow at all.—R. MOORE, *Thorpe Hall*.

THE LORETTE SYSTEM OF PRUNING.

SIR,—Your correspondent "G. C. O.," asks about the Lorette pruning Messrs. Laxtons have carried out the system for some time, as well as myself, but I find it is not so good for apples as for pears, and only for those varieties that fruit on short spurs.—H. BUCKTON, *Cambridge*.

GLORIOSAS.

SIR,—I have for long been meaning to write and answer, or comment on, Mr. E. Brown's letter on gloriosas which appeared in your April 24th number. The gloriosas are one on our commonest wild flowers during the rainy seasons, and one can pick them by armfuls, but when Mr. Brown says they are "an open grassland plant," I venture to disagree. It is true that they persist on the cleared land, and come up in gardens and farmlands generally, but they naturally require the protection and shelter of a hard, low scrub, as they like to climb by means of the leaf tendrils. They adopt coffee very gladly and do remarkably well in the cultivated ground a coffee farm ensures.

But I have also found them thriving very happily right through big indigenous forests (our forests here are practically never

Digitized by Google

"steamy"), and the variety common in Uganda is, I understand, purely a forest plant. I have one flowering in my garden now, about 10ft. of long, thin stem, a lemon yellow flower with dark red blotch down the centre of each petal, and in full shade; while the common one, indigenous here, always does better if planted under a big shrub and allowed to come up through it. But I agree that the cool house should be sufficient for their culture at home, as our climate is very temperate here, never either very hot or very cold. One more point, I have seldom had to dig deeper than 6ins. for the tubers of gloriosas, and often, in cultivated coffee land, the root has come up when one wished only to pick the bloom.

As a distant reader of your paper, I wonder if it would be possible, when new, rare and very desirable plants are written of, to state where they are to be got. I have searched all catalogues for Hibiscus Waimeæ, and for seeds of Argemone platyceras rosea and its hybrids, without success. As many hibiscus varieties are indigenous here and as argemone is apt to become a cheerful weed in Kenya gardens, I should much like to obtain these rarer varieties as they would be likely to do well.—LADY MURIEL JEX-BLAKE, *Nairobi, Kenya Colony.*

WHAT TO DO IN THE GREENHOUSE

Topical Greenhouse Notes.

PERHAPS, during the hottest spells of weather, owners of greenhouses have not entered them often during the daytime. They were content to do the necessary watering and ventilating work. But now the greenhouse is an object of great interest; it is being cleaned out; any plants that can be spared are discarded, because every square foot of stage and border space is required for those valuable plants now ready to be brought in from the bed of ashes outside and from the cold frames. I daresay many readers own greenhouses from the roofs of which climbing and trailing plants gracefully depend. A start should be made with these plants, beginning at the top and finishing at the bottom; but first clear away any pot plants immediately underneath, so that insect pests disturbed on the climbers will not fall on the pot plants but on mats placed on the floor, then all can be shaken off with dead leaves and twigs on the garden fire. Having dealt with the roof plants, finish with those on the stage and, finally, with any that may be growing under it.

Throughout the winter months, as we know, there is a minimum of light, so we should arrange our stocks of plants accordingly. Some will thrive where a minimum of sunlight reaches them—such, for instance, as cinerarias, cyclamen, calceolarias and primulas. Then the schizanthus, zonal pelargonium, heliotrope, bouvardia and similar kinds require the maximum amount of light and should have positions on shelves and high stages well exposed to the light.

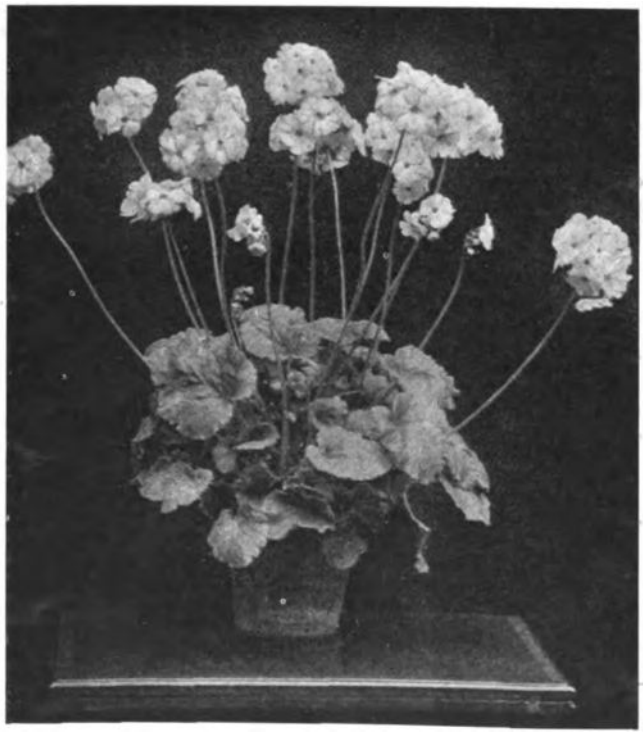
By doing this—it is a case of good management—we get the very best out of all our plants. Having well cleaned the plants and the whole of the inside of the greenhouse, we must also clean the pots and plants that we bring into it; seeing to it, also, that the drainage of each pot is free, unblocking any that is found unsound.

I daresay readers will be anxious to re-pot some of their plants. At this season of the year it is unwise to do so except in certain cases where the plants are really starving in their small pots, then re-potting may be done. In other doubtful instances a little feeding until the end of November will do most good. The watering of the plants should be done in the morning now and until the end of February. Manure water and other stimulants should be withheld from November to February, except in such cases as referred to above.

Then, there will be the question of fire heat. Sufficient should be used to exclude excessive moisture and to maintain a minimum temperature of 42° during frosty nights. It is atmospheric moisture that does so much harm to our greenhouse blossoms late in the autumn and early in the winter. Ventilation should be given whenever the weather permits and the atmosphere should be kept dry.

Finishing and Staging Chrysanthemums.

THERE are some cultivators of these plants for exhibition purposes who succeed well enough with them up to a certain point. I know of several myself. They grow excellent plants which bear grand buds; the stage reached is that where the buds are sufficiently advanced to warrant the removal of the plants to a glass structure and, so far, everything is going well. The next stage is that where the colour of the flowers can be clearly seen, and it is from this point that mistakes are often made. I have heard one grower remark about another, "Oh! he can grow the plants well enough, but he cannot finish them," meaning, of course, the blooms. In the first place, we must remember that the chrysanthemum is, almost, a hardy plant; as a plant it is hardy, but the blooms will not pass through a rather severe frost without injury. This fact teaches us how we should treat the plants and blooms of exhibition varieties while they are under glass. Abundance of air should be admitted up to the stage when the colour of the blooms shows; then less ventilation and less watering and feeding, respectively. But these changes should be gradual and according to prevailing weather conditions. At first there must not be any shading of the structure; from the stage I now refer to there should be a green shading applied to the glass. If there are some blooms backward, then place them in a position by themselves where they can have the benefit of more sunshine.



PRIMULAS ARE FIRST RATE PLANTS FOR LATE WINTER DECORATION IN THE GREENHOUSE.
Give them every attention during the next few weeks.

Feed the plants judiciously until the blooms are three parts developed. Apply water of the same temperature as the interior of the house between the hours of nine o'clock and two o'clock, when moisture at the roots is needed. Always avoid cold draughts blowing directly on the blooms. Be careful about front ventilation, not any in gusty weather. The top ventilators should be open a little even on frosty nights, just a little on foggy nights, and every night have the pipes nicely warmed to expel damp. As a guide see that there is not any moisture on the inside part of the roof-glass.

Nearly every class for cut blooms provides for long stems, too. In cases where a particular prize is being competed for the stems should be placed in cups containing water in the bottom of a box or frame covered with canvas. In ordinary cases provide boxes 9ins. deep, 3ins. wide and 48ins. in length. Lay the blooms in rows in the box, a roll of paper under the stems of each row, and a light lath just pressing on the stems and wedged to the sides of the box. The latter will contain twenty-four blooms with long stems, which will travel well if first placed in water for a few hours and covered with blue paper inside the box. Do not unduly crowd the blooms in the vases. Remove any damaged petals. Have good depth, broad petals, rich colours, good form and perfect freshness in every bloom.

Bringing on the Arum Lilies.

ARUM lilies in pots pay for a little special attention just now in order to bring them into flower at the earliest possible date. Of course, in an absolutely cold greenhouse the plants will make little headway and, unless protected, the leaves may suffer badly from frost. Where a high temperature ranging from 65° to 70° is available, the richardia is easily forced into flower by Christmas, but with much less warmth they can be induced to bloom in the early months of the year. When growth is actively started the arums will require an abundance of water; in fact, the best results are usually secured when the pots are actually standing in saucers of water. Arums very much appreciate weekly applications of liquid manure. The foliage is greatly benefited by syringing, and this will help to keep down green fly, which is often a trouble where these plants are concerned. C.

APPLES FOR PRESENT PLANTING

The time has come round for the ordering and planting of fruit trees. Here is a list of a few good all-round varieties which every amateur should grow.

IT is, naturally, not possible to compile a short list of fruits which will be considered ideal by everyone and, while not professing to have chosen the best in some people's opinions, I can safely say that the following list is composed of varieties which have been found the most successful ones here, and, from what I have seen in various parts of the country, they are among the most successful generally. The newer varieties I have ignored, for, although I have seen beautiful fruits and tasted well flavoured fruits at shows, I have had no experience of most of them, and, being rather cautious, I prefer to rely, for the time being, on well tried varieties and to include the newer varieties when I have had more experience of them.

Beauty of Bath is, perhaps, the best of the very early varieties. A flat apple of medium size with a yellow colour plentifully tinted with red stripes and possessing a fine flavour. Its faults are that it is not a really good cropper and that it drops early—often before it is ripe, and for that reason should be looked over several times. It is also a good plan to place a layer of straw under each tree, so that any fruits which drop may not be bruised. The growth is of medium strength, and it makes a nice bush if carefully shaped; it is liable to grow very one-sided if not regulated.

Irish Peach is not, in my opinion, as good as Beauty of Bath, but it seems to be popular. A somewhat conical fruit of medium to small size, having a pale yellow colour, with a red flush and red stripes. It has a fairly good flavour, but, like Beauty of Bath, it is liable to drop before it is ripe. Owing to the habit of this variety of fruiting on the tips of its shoots, it is generally grown on the "thinned" or extension system—that is, the branches are thinned out instead of being spur-pruned. I have heard of Irish Peach being spur-pruned, but have never seen one, and should imagine it would not fruit freely under this treatment.

Lady Sudeley follows Beauty of Bath and is of similar colour, but is larger and more oblong. There appear to be two types of this variety. The larger of these two has very little red colouring and is rather too large and coarse for dessert; while the smaller is almost covered—at least, on the exposed side—with a bright red flush and broad stripes. Its fruit is of good flavour if eaten as soon as picked, but if kept is liable to get very mealy. The great value of this variety lies in its regular cropping and its fine colour.

Duchess of Oldenburgh is another variety which ripens in August and September. It is also of value for cooking. A medium-size fruit of very pale, almost white, colour, with a few red stripes over the exposed side. The flavour is fair and acid. While young, this variety produces lovely fruits; but as it gets older it appears to contract every disease which is about, being especially subject to scab and canker. For this reason I would not grow it.

Worcestershire Pearmain.—I think I may safely omit any description of this well known variety. Its season is September and early October, and its greatest claims to notice are its regular cropping habit and its fine colour. As for flavour, it is a matter of opinion; personally, I do not care for it; but others I know think it very fine. However, I know all will agree with me when I say it is one of the very best to grow for market.

James Grieve is, to my mind, the best apple of its season, which is late September and October. It is a round conical fruit of a pale yellow colour with red stripes. The flavour is first-class, and its main fault appears to be that it does not colour well in some years. From a marketing point of view it has one other fault—it is soft. It is a good grower, a regular cropper and a nice clean fruit. Here, again, picking should extend over a period, as some fruits mature much earlier than others.

Charles Ross is a good apple which does not seem to be very well known. Rather large, round or flattish (there appear to be two types of this variety), with a greenish colour flushed a reddish brown, this apple has a good flavour and is in season from October to Christmas. As it somewhat resembles Cox's in appearance, the small fruits sometimes find their way to shops under the latter name. Although it does not crop heavily for the first few years, it overcomes this defect when well established, and then bears both regularly and heavily. It is rather subject to attacks of capsid bug, but that is the only fault I can find with it.

Allington Pippin, a conical apple with a good flavour, pale cream in colour, with a slight flush. It is a regular cropper which does not make a lot of growth. Its season is similar to Charles Ross.

Cox's Orange Pippin.—The very best of our dessert apples. In season from November to February, it has an exquisite flavour. In size medium to small, and rather dull in appearance. The ground colour is yellow, with a red flush covered with russet. Its faults are that it is self-sterile and must be planted with other varieties, and that it is very prone to mildew, canker and scab. This apple often cracks very badly with scab.

Gascoyne's Scarlet is more of an exhibition apple than a dessert variety, but its flavour is fairly good. Its season is till January, and its colour is a brilliant red with tiny dots all over it. There is a waxy bloom on the fruit, and its eye is very deep. The flesh is faintly stained with red.

William Crump is another apple which appears but little known, but is now being planted more. Keeping till February or March, it has a conical fruit with a rather dull red skin. Of medium size the flesh is stained with pink right to the core. The growth is very upright, reminding one of a pear tree. This variety obtained a special prize at the Imperial Fruit Show last autumn.

King of Tomkins' County.—A spreading, rather strong-growing variety which crops very well indeed. Keeping till April, this apple is rather large and irregular in shape. The general outline is conical. It is of a golden colour with a bright flush and broad red stripes. The skin is greasy and the flavour very good.

Warwickshire. N. D. H.

OUR SERVICE BUREAU

Though so many subjects are dealt with in each issue of THE GARDEN, *it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, there is always information available from a staff of expert contributors and consultants; and there is no charge for this. It is one of the additional means of service which* THE GARDEN *is glad to render to its readers.*

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope and the coupon, that will always be found in each issue, shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2.*

We have selected the following enquiries, with their answers, as being of more general interest, and therefore worthy of publication.

Babianas for a South Devon Garden.

In the August 14th, 1926, issue of THE GARDEN *there appeared an article on "Babianas at Home," by K. C. Stamford. The writer remarks that these should be capable of cultivation in England. My garden in South Devon is a hot, dry one in summer, and contains a steeply sloping wild bank, which, though facing north, is sheltered by an adjacent quarry and gets a good deal of sunshine. I should be glad to know if you think this plant would flourish here. Our soil is a bright red, very heavy kind, which becomes dry and hard in summer, but is very fertile.—D. L.*

We certainly think you would be successful with babianas in the position in your garden which you mention. They require a very sunny spot, and should do well if they receive protection over the winter.

Kniphofia erecta and its Requirements.

With envy I see the illustration of Kniphofia erecta in your issue for September 25th, page 533. Is this quite hardy? Two plants I had rotted off last winter. I want to try them again, but will wait and hear what you have to say about them. I also lost in the same way C. M. Prichard. My ground is cold clay, but has been very much lightened with loam, leaf-mould and sand.—W. A. S., King's Norton.

Kniphofia erecta does not differ in any way from the other species with regard to hardiness. It requires an ordinary light, rich sandy soil, and a sunny, or lightly shaded, position. Propagation by division of the roots should be carried out in spring. In an exposed position it is advisable to lift and winter them in a frame, or cover the roots with leaf-mould or coconut fibre to keep them warm. That is the only essential to bring them through the winter months. The clayey nature of your soil is probably responsible for the plants dying off with you in the winter.

Division of Perennials and Sowing Sweet Peas.

I want to dig my garden well all over and thin it out. Can I divide and replant now, without harm, the plants one usually divides in the spring—such as pinks, doronicums, violas, London pride, etc.? Also, can I sow sweet peas out of doors now with advantage, also carnation seeds in a conservatory

Digitized by Google

unheated), or shall I wait till early spring?—B. C., Palmers Green.

It is better to lift and divide the plants which you mention now, since you are digging over your whole garden. The majority of herbaceous plants can always be lifted at this time, including such subjects as doronicums, Michaelmas daisies, lupins, etc. Pinks can also be divided, also violas and London pride. London pride is a rapid grower and some care should be taken in not allowing it to get out of hand. Sweet peas can be sown out of doors during the middle weeks of October. Sow in the open ground in a position which has some shelter. After germination, which should be rapid, protect the young seedlings with twigs and branches; not only do these give the seedlings additional support, but they also supply the necessary protection from winter frosts. You will find a very helpful article on this subject in our issue of October 9th. It will probably be better to wait until the spring before sowing carnation seeds, although certain success might be obtained by sowing them now.

A Columnar Cypress.

Could you advise me as to the best type of columnar tree of the cypress type for the Glasgow district? It is essential that it should be of very erect columnar habit and narrow upright growth. Is Cupressus sempervirens hardy in this district, and would it be suitable?—W. K. R.

We suggest that you might purchase Cupressus Allumii. It is a most erect grower and has an elegant habit and glaucous foliage, and should do well in the vicinity of Glasgow. Cupressus sempervirens is quite hardy on the west coast of Scotland and should do well round the Glasgow district.

Flowering Shrubs for Hot Sandy Soil.

I should be grateful if you could tell me of some bright flowering shrubs about 4ft. to 5ft. high that would be suitable to mass in a bed in rough grass in very hot, dry, poor, sandy soil. I do not want either brooms or gorse, or anything white, as I have these. Also I should be glad to know of some bright yellow or blue prostrate and creeping rock plants to put into a rough retaining wall on a bank in a very hot, dry position to flower about June or May. I have Cytisus Ardoini prostrata, C. kewensis, Genista tinctoria fl. pl., G. prostrata, Coronilla iberica and Potentilla Farreri prostrata.—A. C., West Malling, Kent.

We should advise you to give the soil a liberal dressing of rich manure and then plant Forsythia spectabilis (rich yellow), Spartium junceum (yellow), Rubus ulmifolius fl. pl. (pink) and Tamarix pentandra (pink), which will all be suitable for massing in grass. The rock plants we should suggest are Cytisus Beanii (yellow), Rosmarinus officinalis var. prostratus (pale blue), Helianthemum formosum (yellow) and H. vulgare (yellow).

Ripening of Vines.

If a Muscat Hamburgh vine is planted in a house with Black Hamburghs, will both varieties of grapes be ripe at the same time, or should the Muscat Hamburgh be started earlier? Is it true that the Muscat Hamburgh will come to perfection only when grafted on the Black Hamburgh? Will sulphate of iron improve the colour of Muscat of Alexandria if applied to the border? If so, what time of the year is best to apply it?—H. B., Barnwood, Glos.

The variety Muscat Hamburgh will not ripen as early as Black Hamburgh if both sorts are grown in the same structure. The former requires a longer period of growth—similar to that of the Muscat of Alexandria. The Muscat Hamburgh is improved by being grafted on the Hamburgh, as it "sets" its berries better and "stones" a little more freely. In every case, however, the Muscat Hamburgh is a disappointing grape to grow, being deficient in colour and, often, shanking badly. Sulphate of iron will improve the colour of black grapes, as will sulphate of magnesia and sulphate of potash. Half a part of the former, one part magnesia, two parts potash. Fork lightly into the surface soil early in spring, but only give small applications.

Quick-Growing Hedge Plants.

I am anxious to plant a hedge that will screen out the garden from the carriage drive. I thought of planting Cupressus macrocarpa, but am told that it gets very leggy and is altogether unsatisfactory. Do you recommend Thuya Lobbii, and is it very slow growing? I really want to make a hedge that will grow up quickly, as I only rent this place.—K. D. B., Exeter.

Cupressus macrocarpa forms a fine hedge, provided that a sufficiency of space is allowed between the plants, so that bushy growth results. In addition, it is also fairly quick growing. Thuya Lobbii, on the other hand, is much slower in growth. Another shrub which forms an excellent hedge is Berberis stenophylla. It is fairly rapid in growth and forms a bushy hedge, often reaching a height of from 6ft. to 8ft. As well as forming a suitable screen, it is exceedingly decorative, carrying numerous yellow flowers in spring and crops of red berries in the autumn.

Plants for Damp Situations.

We have in our two acres of ground three swampy places, where apparently nothing grows but alders and meadow sweet. These patches we have tried to drain, but they seem full of springs from the hill and are as wet as before the drains were made, and I suppose always will be. Is there anything that would be likely to grow besides what I have mentioned? I dislike alders and of birches we have more than enough already. I think the soil is rather sour, as on the drier parts heather and bracken and blackberries grow. Would any prettily barked willows do, or variegated elders? We tried spiræas, but only some seem to have grown and those not in the boggiest parts. The climate is mild and everything we have planted since coming here two years ago has done well, except, as I say, in these swampy places.—L. B., Aberfoyle, Perthshire.

Before anything will grow well in the sour, swampy ground, it must be drained by means of trenches to carry away the water. Snowy Mespilus (amelanchier), swamp honeysuckle (azalea), Senecio Clivorum, S. Ledebouri, Japanese irises (I. Kæmpferi), I. versicolor, I. ochroleuca, I. sibirica, Caltha polypetala, Lobelia cardinalis, Lysichitum camtschatcense and Lythrum salicaria rosea might be tried among others.

A Compact-Growing Conifer.

I am going to plant a specimen conifer. I would like it to be a neat compact grower, making about 18ins. growth per year and as glaucous as it is possible to get it.—W. A., Dumbartonshire.

We should suggest that you select one of the species of cupressus, which we think will satisfy your requirements. Cupressus Fletcheri is a compact and fairly rapid grower, and is exceedingly handsome with its compact form and bluey green foliage.

Green Gages for Wall.

I wish to plant a few green gage trees against the high west wall of our enclosed kitchen garden and would be glad of your advice as to which varieties are most suitable for this part of the country. Our garden is about 300ft. above sea level in the middle of south Perthshire with a clay subsoil. Early fruiting trees are an advantage here, as in the event of a wet, sunless summer the fruits have a longer time to ripen. We have already a very old green gage tree against part of the wall I refer to which sometimes fruits well, but we have no idea of the variety and the tree is almost done and evidently very old.—M. G., Muthill, Perthshire.

You should plant the old green gage, as the fruits are always so sweet, and Jefferson gage, Denniston's Superb gage, Oullin's Golden gage and Early Transparent gage. Destroy the old tree. Use lime or lime rubble in the soil if it is deficient in lime.

Shrubs for Trellises.

I should be glad if you could tell me any suitable shrubs, flowering or otherwise, which would grow up and cover the netting of a tennis court at one side in order to hide a bad view. The netting is 9ft. high and on the east side of the court. The tennis court is an ash one surrounded by a field of clay soil. Also, could you recommend suitable roses for growing on a trelliswork wood fence only 4ft. high.—A. B., Stirlingshire.

As the soil is clay, this should be trenched 2ft. deep, working in plenty of old builders' rubble before planting the following climbers: Jasminums nudicaule and officinale, Rose Albéric Barbier (which is practically evergreen), Lonicera japonica, Pyracantha Lalandei, if the position is not too cold and bleak. The stronger-growing ivies would make a good screen if you consider them suitable.

Shrubs for Walls.

I have lately moved into a newly built cottage (red brick walls) and want to plant the walls as soon as possible. It faces south-west, and is on high ground in a rather exposed position, the prevalent wind being south-west. I would like to plant Choisya ternata, Ceanothus microphyllus, roses, Clematis Flammula, Virginian creeper, Jasminums nudiflorum and officinale and ivies, but would like to know which aspects would suit best for these. The cottage is about 38ft. long on the south-west side, 24ft. on the south, 38ft. on the north-east. There is a wooden shed at the north end which has an available side for planting on its south-west and north, and on it I would like to have a pear or other fruit tree, and would be very glad of advice as to planting walls and shed, as I do not want to lose time by planting in the wrong places. The walls are a rather bright red, so do not want to put crimson roses on them, but would like some evergreen, like euonymus or pyracantha by the entrance on north-east side, or Garrya elliptica. Would honeysuckle do best on the shady or sunny aspect?—M. B., East Grinstead, Sussex.

We should suggest that you try the following climbers for the walls of your cottage:

For South-west Wall.—Pyracantha, Garrya elliptica, Cydonia japonica, Jasminum officinale and Clematis montana, fast growing.

For South Wall.—Any ceanothus, choisya, Climbing Niphetos rose, Eccremocarpus scaber, Passiflora cœrulea, Solanum crispum—the three last named are fast growing.

North-east Wall.—Virginian creeper, Jasminum nudiflorum, Rose Gloire de Dijon, Clematis Flammula and C. Jackmanii, ivies and Forsythia suspensa. The honeysuckle (Lonicera japonica) would probably be the best evergreen climber for the north-east wall by the entrance.

For the shed we suggest that you try Pear Williams' Bon Chrétien at the south-west end and Morello cherry at the north end.

NEW HARDY CRIMSON BROOM

Chelsea Show (1925) the King said, "That red Broom is certainly very striking." This the new crimson Broom "Dorothy Walpole," received the unanimous Award of Merit the R.H.S. as well as other distinctions in on and on the Continent. Plants have been o U.S.A., Canada, Australia, New Zealand, ce, Holland, etc.

the Field, a well known ex-Curator of Kew lens wrote: "The richest coloured Broom n is one named 'Dorothy Walpole.' It is rdy as the common Broom . . . and is free-flowering . . . the colour is rich ty crimson . . . more attractive than of the coloured Brooms yet seen." The colour urpasses Cytisus Dallimorei, and the growth vigorous as C. Andreanus; it requires no al treatment nor any kind of protection ever—just a hardy shrub for ordinary garden in any part of the British Isles, however far

Vice-Chairman, Floral Committee, R.H.S., e: "Everyone who has seen my plant has astonished at its warm glowing red"; and a lady in Devon: "I am so delighted with Broom 'Dorothy Walpole.' It has done diddly and is like a sparkling gem in the garden a mass of flower."

Small Orchards

No matter how small or large the orchard, it pays to use Stictite Tree Banding Compound.

Winter Moth rises from the soil early in October or late September, and the females (being wingless), at once crawl up the tree trunks in order to deposit their eggs in the branches.

By banding the trees with Stictite in the autumn you can prevent the eggs being laid, and so avoid having to spray for the caterpillars in the spring.

1 lb. of Stictite will do 9 to 12 trees of about 8 in. diameter.

½-lb. 1/6 (post 6d.); 1-lb. 2/9 (post 6d.); 2-lb. 5/- (post 9d.); 4-lb. 10/- (post 9d.); 7-lb. 17/6 (post 1/-).

Greaseproof Paper, 5 ins. wide: 6 yds., 2d.; 12 yds., 3d.; 25 yds., 6d.; 50 yds., 9d.; 100 yds., 1/6; 200 yds., 2/6.

Write for Descriptive Folder.

Stictite is sold by Nurserymen, Seedsmen, Florists, Ironmongers, Chemists & Stores. If any difficulty, please write to Abol Limited, 9, Baltring, Paddock Wood, Kent.

HOW DIGGING AND TRENCHING SHOULD BE DONE

ORDINARY digging is turning the soil over one spit deep; trenching means turning it over two or more spits in depth. But we will first deal with ordinary digging. If ground is uneven on the surface it can be levelled very much by judicious digging, carrying out the work with one's face to the higher ground, is the easiest way, but not the best, if the surface is uneven. Always begin at the lowest point and finish at the highest. If you begin at one corner, intending to finish at the one directly opposite, there is no need to move over any great bulk of soil. But to afford freedom for the work it is a wise plan to move one barrow-load of soil with which to fill up at the opposite corner when the digging has reached that point. If, however, the whole of one side, or end, of a plot is being dug across, then it is necessary to remove a spit of soil right across and take it to the side or end where the work is to be finished. Where clayey soils obtain, a strong garden fork is a better tool than a spade, as it is easier to insert and leaves the turned-over soil with a more broken surface than a spade would. Moderately light and sandy soils are easily turned with the spade. Whether spade or fork be used the tool should be driven in straight down and not at an angle of about 45 degrees as one often sees it done. The straight-down drive, with leverage towards the workman, raises an almost square-shaped lump of soil, which, when turned over remains lumpy on the surface, open, too, admitting rains and air freely; and at the end of the winter the whole bed is readily broken up in a mellow state and made fit for the planting or sowing as required. The soil soon pans down hard again when the spade is inserted in a slanting direction and the soil is turned over in thin slices. Dig a course right across the plot, returning so, to and fro, until the plot is dug. If there is any uneven surface, watch it carefully and level as the work proceeds.

Trenching.

By this, as I have said, is meant digging the soil two, or more, spits deep. If two spits, two layers of soil are turned over, but, usually, kept in their positions as regards surface and distance below it, and at the bottom of the two spits the sub-soil is thoroughly broken up with the garden fork and left below. If trenching is done more than 2ft. in depth a wider open trench is necessary, and three spits of soil must be turned over, the sub-soil being loosened in addition. With regard to bringing up the sub-soil in any quantity, opinions vary as to the merit of the system. I firmly believe it is best to leave it below, as some of the good top soil is sure to fall down and mix with it every time the ground is deeply prepared for cropping. The plot should always be divided into two parts for trenching; the soil removed from the end of one part is placed at the end of the other part abreast and used for the final filling-in when the second portion of the plot is finished.—G

SOCIETY NOTES.

THE Council of the Royal Horticultural Society is desirous of drawing attention to the Jones-Bateman Cup. This cup was presented to the R.H.S. in 1920 by Miss L. Jones-Bateman of Cae Glas, Abergele, and is a valuable silver-gilt replica of the Warwick Vase. It has been decided to award the cup for the encouragement of fruit production. It is offered triennially for researches in the growing of hardy fruits, figs, grapes and peaches in the open or under glass.

Candidates should submit accounts of their work by October 31st of the appointed years. The work dealt with must have been carried out by the candidate in the United Kingdom mainly during the preceding five years. The cup will be held for three years by the successful candidate, who must give a bond for its safe return.

The assessors shall be two appointed by the Royal Horticultural Society and one by the Federation of British Growers, who shall report to the R.H.S. Council upon the originality and comparative potential value to the fruit-growing industry of the work of the candidates.

It will be seen that candidates account of work must be submitted by October 31st this year and the Council sincerely hope that there will be a response from those interested in fruit culture.

The Annual Orchid Show.

THE annual R.H.S. Orchid Show will be held in the Society's Hall at Vincent Square, Westminster, S.W.1, on October 19th and 20th.

The Baron Schröder Challenge Cup will be awarded for the best group of orchids exhibited by an amateur; no restriction as to the number of assistants or area. A challenge cup value 20 guineas, presented to the Society by the Trade Orchid Growers for competition, will be awarded for the best group (60 square feet) exhibited by an amateur who employs not more than three assistants. A silver trophy, valued 7½ guineas, for the best twelve orchids, not more than two of one genus, exhibited by an amateur who employs not more than two growers in his orchid house.

The Secretary of the R.H.S. will be pleased to receive entries for these competitions and to supply entry forms. Entries should not be received later than by the first post on Monday, October 18th.

The National Rose Society.

THE dates of the National Rose Society's shows in 1927 are as follows:

The Spring Show will be held at Vincent Square, Westminster on Friday, April 22nd; the Summer Show in London on July 1st and 2nd; the Provincial Show at Cheltenham on July 6th and 7th. The Special Show of New Seedlings, at which the *Daily Mail* Cup will again be competed for, will be held at Westminster on July 15th, and the Autumn Show at Westminster on September 9th and 10th. It has been decided by the Council to hold a Rose Conference in London in July, 1928. An announcement as to the arrangements will be made later.

TRADE NOTE.

The home gardener is often at a loss to know how to enclose his flower borders, garden paths and lawns in such a manner as will show these off to the best advantage and, at the same time, ensure perfect tidiness in the garden. The work can be much simplified by the use of "Bordex" patent garden edging, manufactured by The Millbrook Manufacturing Company, London, E.C.4, sold in yard lengths that interlock in such a manner that perfect rigidity and alignment is preserved. The finished appearance is pleasing, giving the effect of tiling, at very much lower cost and infinitely less trouble. "Bordex" is made of weatherproof metal, finished in dark green or in terra-cotta, the top edge being rounded over and having vertical corrugations that enable the edging to be bent to fit any curve or angle. On the lower edge are stout, sharp spurs, which are inserted into the ground merely by pressure of the hands. This edging allows for a depth of 2¾ins. above the level of the path or border, while the saving in labour when it is used to edge lawns is very considerable, because it can be pressed down to a level which will allow the mower to pass over, and the edges of the grass will no longer need trimming by hand.

WAKELEY'S *Celebrated* Hop Manure

REGISTERED

THE ORIGINAL AND ONLY RELIABLE SUBSTITUTE FOR STABLE MANURE

DIPLOMA AND MEDAL, ROYAL INTERNATIONAL HORTICULTURAL EXHIBITION, 1912.

DO YOU REALISE IT?

A large bag of WAKELEY'S PATENTED HOP MANURE at a cost of only 7/- carriage paid to your door (if within 25 miles radius of London, or at a trifling extra if beyond), GOES AS FAR AS A CART-LOAD OF STABLE MANURE, without any of the defects of the latter; gives better results, is easy and clean to use.
Every ounce of Wakeley's Hop Manure is of value to the soil, supplying the necessary HUMUS in addition to the valuable plant food. Worthless rubbish is not added to make weight (as is the case of some artificial manures advertised).
Thousands do realise it, the proof of this is the constant flow of UNSOLICITED LETTERS received from time to time in praise of the wonderful results obtained at such a moderate cost (see Catalogue for selection).

BEWARE OF IMITATIONS.—Genuine only in our Marked Bags, containing Guaranteed Analysis.

Nurserymen, NORWICH, NORFOLK

Notes from Maidstone.

CAPE PLUMS.

This group of Plums is descended from Prunus salicifolia, a Chinese species, but the exports from South Africa during the winter have led to the name given above. Not hardy enough to fruit outside in this country, they are most interesting orchard house plants in pots or trained on walls, and we offer three varieties: Abundance (Burbank), golden yellow and red; Botan, garnet red—the best flavoured; and Shiro, golden yellow, of enormous size. All are rather early ripening. Bushes and Fans are 7/6 each.

George Bunyard & Co., Ltd., The Royal Nurseries, Established 1796. Maidstone.

NEW HARDY CRIMSON BROOM

AT Chelsea Show (1925) the King said, "That red Broom is certainly very striking." This was the new crimson Broom "Dorothy Walpole," which received the unanimous Award of Merit from the R.H.S. as well as other distinctions in London and on the Continent. Plants have been sent to U.S.A., Canada, Australia, New Zealand, France, Holland, etc.

In the Field, a well known ex-Curator of Kew Gardens wrote: "The richest coloured Broom known is one named 'Dorothy Walpole.' It is as hardy as the common Broom . . . and is very free-flowering . . . the colour is rich velvety crimson . . . more attractive than any of the coloured Brooms yet seen." The colour far surpasses Cytisus Dallimorei, and the growth is as vigorous as C. Andreanus; it requires special treatment nor any kind of protection whatever—just a hardy shrub for ordinary garden soil in any part of the British Isles, however far north.

A Vice-Chairman, Floral Committee, R.H.S., wrote: "Everyone who has seen my plant has been astonished at its warm glowing red"; and from a lady in Devon: "I am so delighted with the Broom 'Dorothy Walpole.' It has done splendidly and is like a sparkling gem in the garden—one mass of flower."

NEW SEASON'S PRICES.

Strong pot-grown plants now ready for planting out, to flower in May, 7/6 each. Carriage paid rates to any station in Great Britain or Ireland: One plant, carriage paid, 10/-; two plants, carriage paid, 18/6; three plants, carriage paid, 26/-; six plants, carriage paid, 49/6; twelve plants, carriage paid, 99/-.

Coloured illustration sent on application if THE GARDEN *is mentioned.*

RULES.

1.—A list of your choice of the six most popular climbing roses to be sent in in order of preference on the coupon to be found on page x. of this week's issue of THE GARDEN. A coupon will also be found in last week's issue.

2.—No reader may win more than one prize, but they may send in any number of lists, provided that they are written on the special coupon to be found in this and the next issue.

3.—Coupons must reach this office not later than Tuesday, October 26th.

4.—Envelopes must be marked "Competition."

5.—The popular vote will be final and no correspondence will be entered into over this competition.

6.—The result will be announced in the issue of THE GARDEN, November 6th.

7.—The Editor's decision on all points is final.

Plants in Rooms.

FEW things add so much to the appearance of the inside of the house as a number of well chosen foliage plants, to which flowering specimens are added according to season. It may be said at once that the conditions obtaining in a house are not ideal from the point of view of a plant. In spite of this, given a certain amount of care, many specimens will do well and continue in a healthy state for a long time. Of course, if one is so fortunate as to own a greenhouse, it is an excellent plan to let the plants have spells in this. Thus, after a fortnight in a room, any plant would be all the better for a month's holiday in the glasshouse. Where the specimens have to be kept in the house all the time, it is a very good thing to move them about every few days. Plants that seem rather unhappy in a north room during the dull days of winter, should be given a chance to recover in a sunny southern apartment. Even the simple plan of turning round a pot, now and again, will often help a great deal, for this enables an equal amount of light to reach all parts of the specimen. Plants give sure warnings of gas leaks. If foliage specimens never seem to do well in a room, no matter what is done for them, it is safe to assume that there is a gas leak somewhere.

Another point of the greatest importance in connection with room plants is the question of watering. Carelessness in the direction of giving too much will do more harm than allowing too little moisture. In the winter, when few plants are growing actively, not much water will be needed, certainly not more than is sufficient to keep the soil from becoming dust dry. In the growing season, of course, more moisture is required, but even here do not keep the soil in a continually wet state. The old plan of tapping the pot with the knuckles will often give helpful indications as to whether water is required or not. If the sound is sharp and hollow, the soil is certainly dry right through; on the other hand, a dull note indicates a moist condition of the pot contents. In watering always give sufficient to moisten the whole of the soil. Fill the pot up to the rim each time and then wait until the soil is getting dry. If a plant never does seem to dry up properly there is probably something wrong with the drainage. Here it is a good plan, even in the winter, to deal with the matter at once. Tip the plant right out of the pot, loosen the soil a little at the bottom, and then re-arrange the crocks, adding a few more if this seems needful. After this keep the plant in the warmest and sunniest room in the house for a week or so.

Palms, and other foliage plants, suffer very much from dust when fires are burning. It is a good rule to sponge the leaves at least once a week with lukewarm water. When the weather is mild and rainy these specimens will benefit greatly by being placed out of doors for a few hours. The writer has found that palms, especially, benefit very much if the leaves are washed with a solution of equal parts of milk and water. Note, the milk must be fresh.

HAVE YOU

¶ *Prepared your beds for rose planting?*

¶ *Sent off your plant order? Remember that the best specimens are secured by ordering early.*

¶ *Housed all tender bedding plants?*

¶ *Potted Spanish irises, ixias, fritillarias and early flowering gladioli for spring flowering in the greenhouse?*

¶ *Transplanted your evergreen shrubs which need more room?*

¶ *Stored your late varieties of apples?*

¶ *Pruned your gooseberry bushes and given a dressing of finely ground lime to your plums and cherries?*

¶ *Lifted your seakale for forcing?*

¶ *Mulched with rotted manure your fruit trees which have borne heavy crops?*

Mr. T. W. Sanders.

IT is with the greatest regret that we have to announce the death, on October 14th, of Mr. T. W. Sanders, F.L.S., F.R.H.S., editor of our contemporary *Amateur Gardening*. Mr. Sanders was the Grand Old Man of British horticultural journalists, and his death at seventy after a short illness is a great loss to British gardening. He was born at Martley in Worcestershire, and from boyhood showed an aptitude for gardening that has certainly borne fruit. After an ample practical training he was appointed editor of *Amateur Gardening* in 1887, a post which he worthily filled since that date. The small amateur gardener owes more than he imagines to Mr. Sanders' foresight and help, for he has always been a firm believer in popularising the best types of plants that are easily grown by the man who looks after his own garden. Mr. Sanders was the author of nearly forty volumes, all of which were written to help the small gardener. He was considered as a great horticultural expert throughout the whole of Europe, and in 1906 King Oscar of Sweden made him a Knight of the First Class of the Order of Vasa.

SHRUBS FOR THE SMALL GARDEN

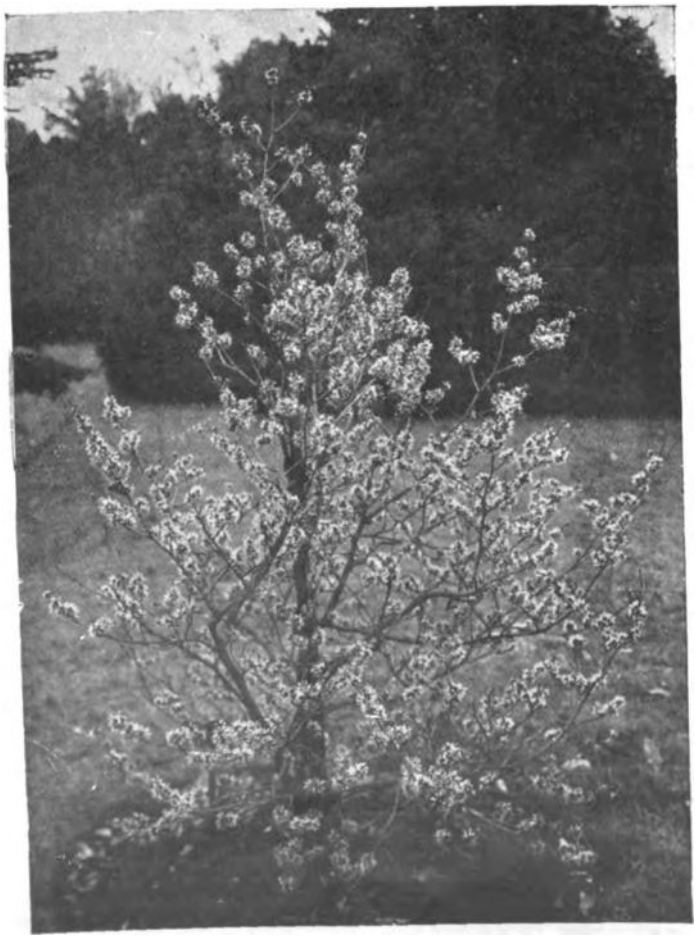
A continuation of the article in our issue of October 16th which dealt with flowering shrubs that are suitable for the average garden.

IN many old cottage gardens in the North you will find fine bushes of the old-fashioned Daphne Mezereum, sometimes called the Mezereon. It is always a most attractive shrub in February and March, when its bare twigs are covered with clusters of almost stemless maroon or white flowers. It apparently succeeds better in the North than in the South, and we should recommend gardeners in the North and East to try it. It is particularly suitable for small gardens, as it is a neat grower up to about 4ft., and does not take up much space. Another shrub which no garden should be without is some form or other of the deutzia. The varieties are numerous, but all are good in that they are graceful growers and are very floriferous. Good varieties, reasonable in price and easily obtainable, are crenata fl. pl., a fine double pink; discolor grandiflora, rose fading to white; gracilis Boule Rose, rosy white with a pink reverse; and Vilmoriniana, a large-flowered white.

Among the best of all evergreen plants for planting against the house are the escallonias. These South American shrubs are good examples of plants that are not quite hardy in the open and yet are very handy when planted under the shelter of a wall. They are really among the best wall plants that we have, for they are quick growing and yet are easily kept within bounds. Three good varieties are the old exoniensis with white flowers faintly flushed with pink; langleyensis, bright rose; and the newer edinensis or Edinburgh variety, of a deeper rose and with slightly larger flowers. Forsythias were mentioned in THE GARDEN a week or two back as useful porch plants, but they are also excellent for the open. The golden bell, Forsythia suspensa, and its hybrid, F. intermedia, are among the best March-flowering shrubs that we have. Their growth is charming, they do not take up too much room, and their golden yellow flowers, produced in clusters on the bare wood, invariably please all who see them. In addition, they last a long time. In the forsythias we have a most useful spring shrub.

Rather low-growing and spreading is the Spanish gorse or Genista hispanica, but it is so covered with bloom in May and June that it is well worth a place even in the smaller gardens. Many authorities call it an indispensable shrub. It does not grow very fast, and so gardeners who have to conserve space need not be unduly alarmed. Its neat, compact habit makes it an admirable subject for a foreground or for the corner of a bed under the house. Although still rather expensive, the two witch hazels that are commonest in cultivation are well worth growing for their curious shaped narrow-petalled flowers that appear on the leafless twigs while winter is still with us. The cheaper of the two is Hamamelis japonica, with yellow flowers; but the better of the two is H. mollis, whose colour is much more golden—it has a much more picturesque growth. Their habit is always good, and their foliage, like our own hazel, is pleasant throughout the summer. Unfortunately, they are rather difficult to propagate, which explains their cost.

DEUTZIAS ARE INVALUABLE IN ANY GARDEN.



A BUSH OF HAMAMELIS MOLLIS IN EARLY SPRING.

Perhaps St. John's worts are hardly suitable for the small garden owing to their spreading habit and their untidy appearance in late autumn; but one variety is worth growing, even in the smallest area. That is Hypericum patulum var. Henryi, which is the best of the St. John's worts, with flowers of a magnificent golden yellow, larger than others, and more handsome foliage. In addition, it is one of the hardiest of the genus, and so is not inclined to look so untidy during the winter months. It will grow to about 3–4ft. in height.

As a wall shrub for against the house, the famous old Jasminum nudiflorum cannot be missed. It flowers so pleasantly throughout the darkest months and is so absolutely hardy that at least one plant should be grown against every house. It flowers better if grown against a south or west wall where it can get the maximum amount of sunshine; but even on a north wall it will provide a sprinkling of its charming yellow flowers throughout the winter months.

A shrub that is rapidly coming into favour is Kalmia latifolia, a native of the United States. For those whose soil is lime-free this is one of the most floriferous evergreens in existence. The flower is saucer-shaped and five-lobed, and is usually of a bright rose. As these are produced in numerous clusters, the sight of a bush in full flower is magnificent. The only fault it has is that it is slow-growing, but it has a neat habit and so is invaluable for small gardens. It should be planted in the sunniest corner, as most flower is produced when the wood is well ripened. It is absolutely hardy, and its uncommon colour and free flowering habit make it invaluable.

Magnolias are usually plants for the large garden, but there is one that is always worth a place in the small garden. This is M. stellata. It rarely grows beyond 12ft. in height, and its white flowers are a sight in March on the leafless branches. It is about the hardiest of the magnolias, but should be given as sheltered a corner as possible without being over-shaded. Another white-flowered shrub that is well worth growing is Olearia Haastii, the New Zealand daisy bush. This bushy shrub that grows to about 6ft. is charming with its greyish foliage, particularly when it is covered in July and August with thousands of white daisy flowers. This shrub is quite hardy and is altogether an admirable plant. Another suggestion for this plant is to grow it

Digitized by Google

as a hedge plant. Flowering hedge plants are rare and its thick bushy growth can be moderately pruned in the spring.

A new shrub that is a magnificent addition to any garden is Osmanthus Delavayi, an evergreen of about 5ft., of good habit and with neat box-like foliage. In addition the flowers are charming, clusters of small white tubular flowers that are very fragrant. Although still a little expensive, yet it is an excellent grower and will certainly become one of the most popular of all shrubs. E. C

PLANTS AT THEIR BEST IN AUTUMN

Gardeners are always glad to receive information about plants that have been particularly noted in other gardens. Week by week plants that are really worth growing are described in this page.

Lobelia Huntsman.

UNTIL really keen frost appears I shall have Lobelia Huntsman still blooming, for since the central spikes faded the laterals have carried on gaily, and many buds yet remain to open.

If one sees a group of Lobelia cardinalis or the old favourite variety Queen Victoria in full bloom, the impression forms itself in one's mind that surely here is the most brilliant colour of which flower can be capable; but when Huntsman, at its prime, is brought into comparison, it is like bringing an electric light beside an oil lamp.

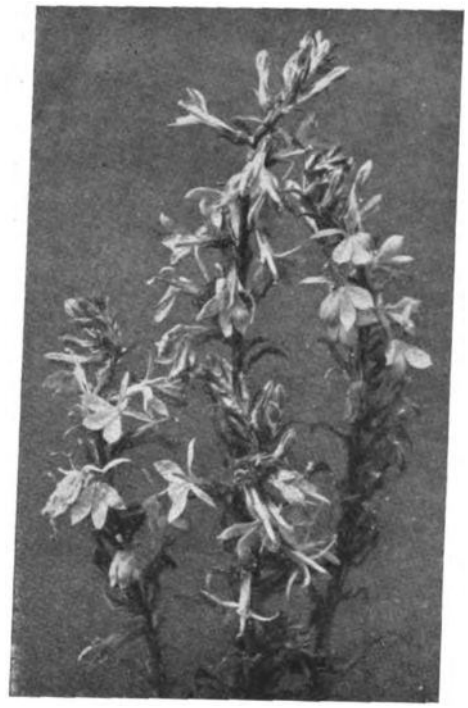
It was in July that my plants began to open flowers; it is now October, and still flowers are opening daily, not so large or dazzlingly bright as they were, but the colour is wonderful still. The central spikes ran well-nigh 6ft. high, and their flowers were individually of great size. The accompanying illustration is of lateral spikes, taken when the bigger flowers had passed, but showing the honest value of the plant for late autumn flowering.

The foliage of Huntsman is green, with a glaucous tomentum, and this helps to accentuate the brilliancy of the flowers better than the mahogany foliage of Queen Victoria.

The "Monarch" Sunflower.

WHETHER or not the plant is properly named Monarch or should be called Helianthus sparsifolius I am not disposed to debate, but it certainly merits the title of Monarch of the Perennial Sunflowers. It is many years since I grew Helianthus sparsifolius, and thought it then much superior to the Harpalium Miss Mellish, which had a great run of popularity; but when Maurice Prichard first showed Monarch I ordered it and have been well pleased. It is flowering as I write as though October were the sun's great month, and even on a murky day the outlook is made more cheerful by the sight of this grand sunflower with its strong stems towering 8ft. or 9ft. high and carrying great golden flowers which are too elegantly built to look coarse, as most large sunflowers do.

There are soils wherein the fleshy roots of this plant rot in winter, but it is generally after they have been gnawed by ground pests. Lime, or a soil fumigant, will preserve many roots from injury; but, rather than risk loss of stock, it is well to resort to the very simple expedient of lifting a few roots as soon as flowering is over, packing the stoutest of the claw-like tubers closely in a box of sandy soil, and wintering in a cold frame. Early in spring these roots may be planted out, giving them all the room that can be spared. It is thus that the strongest stems and finest flowers may be produced.



LOBELIA HUNTSMAN IS WORTH GROWING FOR AUTUMN EFFECT IN THE GARDEN.

An Arum for the Small Garden.

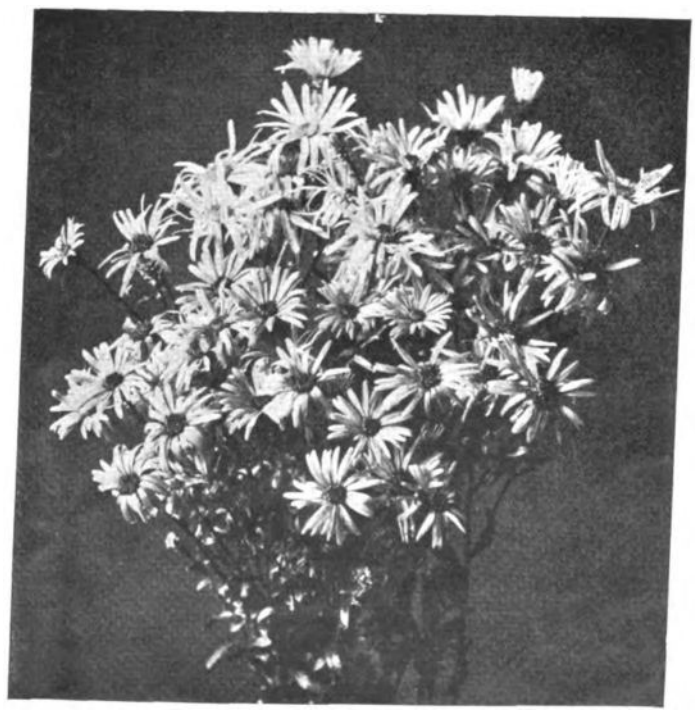
THE closely packed spikes of shining, real orange-coloured berries of this plant constitute a more striking feature in a moist boggy spot than anything else to be seen at this late period. Bigger plants, bushes and trees are carrying berries and making a fine display, but for the most part they are showy because they are massive, and, moreover, they are familiar; but in Arum orientalis we have a small plant which nestles where it may come suddenly and unexpectedly into view. Its short stem only lifts the berried spike clear of the rough grass against which the vivid orange, the glassy polish, and the altogether uncommon character of the berries are thrown into relief with more effect than if they were lifted high above their surroundings.

One of the Finest of Autumn Flowers.

THERE is no question about it, we have in Gentiana sino-ornata a plant to make much of; it is a grower. At any rate, it has flowered well for seven or eight weeks. In point of beauty it is well worthy of its illustrious family. Advice I received from a competent source was that brown peat and leaf-mould should alone form the compost for its pocket on the rockery, but I have since seen it thriving in an entirely satisfactory manner in a bed of gritty garden soil over which a layer of ashes from the rubbish fire was spread before turning over the soil in readiness for planting. Let no one who has decent soil and good drainage hesitate to plant this gentian under the supposition that it must have a special bed made up to carefully calculated formula—the plant is a grower.

Hemerocallis Sir Michael Foster.

ONE of the largest as well as brightest of the day lilies, this variety is adding to its value by continuing to open fine flowers as though its season knows no end. True, we have experienced an exceptional autumn, but it is well worth planting this hemerocallis even for its earlier flowers, and if its behaviour this season is repeated more or less regularly it will be a plant of unique value. Its size singles it out among the best of its family; its colour is bright as yellow can be, and the foliage adds both in graceful form and pleasing colour to the fine effect produced now that good things are becoming scarce.



ASTER ULTRAMARINE.

One of the best of Michaelmas daisies for interior decoration.

Aster Amellus Ultramarine.

THE chief reason why this variety of a tribe that is rich in jewels deserves special mention is that it follows the best of its section, King George, and thus avoids a sudden feeling of loss when useful flowers for the house are in constant request.

Ultramarine is small by comparison with King George, but it is wonderfully neat in a vase, and its colour is very bright blue. In the garden it has a radiance which makes it most pleasing of all when daylight fades to dusk or twilight, and it is different from some blues in that it is bright and lively under electric light. Like all the asters, small young plants give much better flowers than older clumps. A. J. MACSELF.

FLOWER GARDEN NOTES

New Flowers worth Growing.

CORRESPONDENCE columns do much good when thrown open to opinions on the "new things" every gardener tries, for no better guide exists than the experience of others in addition to one's own. Gardeners are always on the look-out for improved varieties of the really useful garden flowers, but, as conditions vary widely over the country, writers should always state where the plants were grown.

Calliopsis Dazzler.—This is a fine bedding variety of the common genus, a little taller than the popular Beauty and even more prolific. The warm July suited it well, and for many weeks it has been a striking splash of colour—yellow and brownish crimson. The lasting nature of the flowers is another feature.

Brompton Stock Monarch.—Most gardeners know the common failings of the Brompton stocks, but in this variety they will be pleased to note an absence of most. The colours are fine; I actually had 85 per cent. doubles, and the plants in bloom were delightfully uniform, both individually and collectively.

Aquilegia Dobbie's Hybrids.—I do not desire to laud these varieties generally, as I have had equally fine plants from other sources; but must say that the reds which came from my mixed seed were exceptionally fine. They were of many tints, from the palest pink to a deep distinct colour, and all were delightful.

Calceolaria Albert Kent.—I grew these out of doors and the fine summer suited them well. The plants remained rather dwarf with me, but the colouring was very rich and effective.

Dahlia White Coltness Gem.—Although I am not so very enthusiastic about virginalis, described as a white Coltness dahlia, yet I must admit that it is fairly good; the habit of the plants being particularly fine and the flowers freely produced. The rains in mid-August spoiled it (I am too near Glasgow), but it ought to succeed better in the country.

Coltness Hybrids.—Trying out some new Coltness Gem hybrids, I may say that I rather like Patrician, Zenobie, Titian and the above virginalis; improvement will surely be made, but as they stand they are worth a place. Not one of them, in my opinion, is quite equal to Coltness Gem itself.

Giant Zinnias.—I wrote in praise of the giant dahlia-flowered zinnias last year, and I can only repeat that they are really fine things. They are particularly fine where effective and good-sized flowers for cutting are desired, and have proved to be as easy to grow as the usual run of half-hardy stuff.

Sidalcea hybrida Ruby—This is a charming improvement of the old perennial sidalceas; the flowers appear at mid-summer and continue in pleasing profusion right up till frosts come. The colour is a ruby red and attractive.

Some Lupins.—There is no need nowadays to have nothing but blue, white, and the more recent pink lupins in the border. Here are a few real gems, perhaps not novelties, but comparatively new in some districts and worthy of a prominent place in all gardens: Somerset, yellow; Sunshine, a clear deep chrome yellow; Queen Amelia, a deep purple; Southern Belle, mauve shaded lavender; Downer's Delight; Wargrave Beauty; Dresden China; Queen of the West; Fascination; Mayflower; Primrose Queen; May Princess, and many others.

Echium plantagineum.—This is a fine annual for showy purposes, the flowers being large and tinted vividly. I used them as dot plants to pack tightly a long herbaceous border (perennials mostly), and the plants bloomed from the end of June right on.—H. A.

A Fine Yellow-Flowered Clematis.

DURING August and the greater part of September, unless we get premature frosts, one of the most attractive corners in my garden is a bit of old stone wall topped with wooden lattice which (and also, I regret to say, a neighbouring bush of Cistus ladaniferus), is completely veiled with Clematis orientalis, covered with its little drooping golden yellow flowers interspersed towards the end of its long flowering season with silky grey seed heads that are very pretty in themselves. This clematis introduced into England nearly a century ago, has never obtained the popularity it merits, probably by reason of its lack of showiness compared with its large-flowered relatives. It is easily raised from seed, though its growth is rather slow at first, and is quite hardy in a dry, sunny position sheltered from cold winds, but in a cold, exposed place it needs some root protection in winter. Its worst fault is its tendency to twist itself—after the manner of C. montana, only more so!—into a dense thicket, so that any serious attempt at training or pruning is out of the question and it is wisest to leave it severely alone. C. orientalis is apt to be confused with C. tangutica, but according to Mr. Robinson ("The English Flower Garden"), the latter is spring-flowering and of a deeper yellow. I do not know it, myself, however.—R. E. HEAD.

LUPIN DOWNER'S DELIGHT. A BEAUTIFUL VARIETY WORTH PLANTING THIS AUTUMN.

A Few Red Michaelmas Daisies.

ONE of the earliest varieties to bloom is Walkden Pink, a fine rose coloured flower of the most charming kind, with clearly defined flowers of a semi-double nature. Grace Darling is much later, very good also, but not such a refined flower as the former; the colour is a lighter pink. Edna Mercia is a much more decided red. Aldenham Pink, another excellent rose red sort, is just to the late side very often, but when it does get a chance to blossom well, it gives the greatest satisfaction. Mrs. F. Penn we also like; the plants are not so tall as many, but they bloom with the greatest freedom and the colour is rose pink. Those who prefer singles may try the large-flowered Ethel Ballard, a soft pink, very fine in vases. Rachel Ballard is double, but a fine sister flower. In the Angliæ group one finds Rosy Morn, Mrs. Raynor, Ryecroft Pink and Rubrus, the last being exceptionally tall and just, too late to succeed in a stormy October. Perry's Favourite, Esther and Formosus sum up the reds we have in these delightful late-autumn flowers.—LANARKSHIRE.

Spanish Irises.

THE merits of this delightful bulbous iris are such that it is deserving of much wider general cultivation than it at present receives. An ideal plant for the amateur, it is of easy cultivation and is exceedingly useful for planting in beds, for grouping in borders, and for the production of cut bloom. In addition to this, the bulbs are quite inexpensive and may be purchased in named varieties for 4s. or 4s. 6d. per 100, while mixed colours cost even less.

The bulbs may be planted any time from September to December, although it is better to get them in before this latter date. Plant 4ins. or 5ins. apart and 3ins. deep. For cut flowers they may be planted in double rows 5ins. apart, allowing 1ft. between each double row; but for garden decoration plant in clumps of about twenty bulbs each.

They thrive in a rich, dryish soil and do not object to a little shade. In open, exposed positions they should be sheltered from cold east winds. Keep free from weeds and give applications of liquid manure when the flower buds begin to develop. Every third year they should be lifted as soon as the foliage has died down, the bulbs sorted according to size, the ground manured and deeply dug, and the largest bulbs replanted. The smaller bulbs may be planted separately and will soon develop into flowering size.

This iris may also be grown in pots, placing six bulbs in a 6in. pot filled with a rich, light compost. Plunge outside under ashes or sand, and do not introduce them to any artificial warmth until the flower spikes show.

Excellent varieties are Canary Bird, bright yellow; Cornflower, lovely blue; King of the Blues, dark blue; Snowball, pure white; Thunderbolt, rich bronze and yellow; and Leander, a deep yellow, sweetly scented variety.—T. H. E.

THE JOY OF MAKING A NEW GARDEN

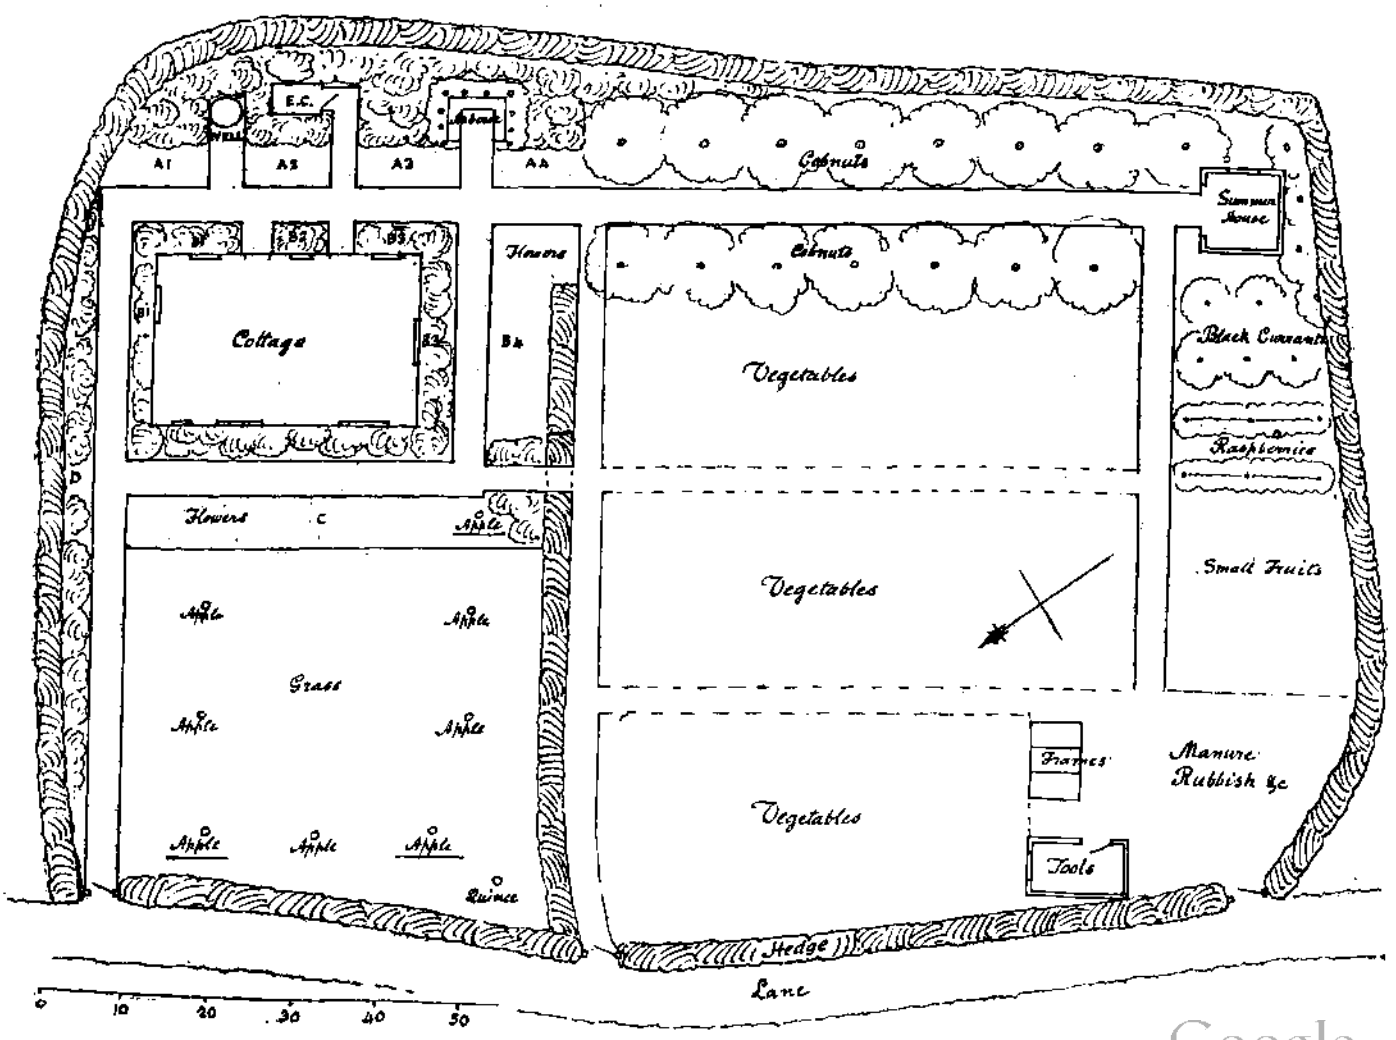
BY GERTRUDE JEKYLL.

In this article, with its accompanying plan, Miss Jekyll treats a site entirely different from those already published.

THIS plan shows a quite different site and character of house from those that have gone before. It is an old thatched cottage, such as, in some unfortunate recent cases, has been condemned as unfit for habitation and has been destroyed. But such a cottage in good hands can not only be made structurally sound, water-tight and wholesome to live in but will have a charm, both inside and out, such as can hardly be acquired by any new building.

The space is something under half an acre; it is surrounded by an old bank and hedge and has another hedge, parallel with the one on the north-west side, that runs up to near the cottage. It is proposed to treat the place according to the plan. The whole sentiment is that of a small, old world country dwelling, sweet and modest, quiet and restful. There is no door in the front face, the main door is at the back, between B 1 and B 2; the kitchen door is next beyond it. Tradesmen come up the middle path that runs next to the dividing hedge on the side next to the vegetable quarters. The front windows look out on to the flower border C; beyond this is a grassy space with apple trees. There is one existing apple just to the right as you enter, one more farther along and another at the end of the flower border; the others shown will be planted. The existing apples are underlined. A quince will come well in the lower right hand corner. At the back of the cottage next to the hedge there is already a planting of small trees and shrubs, shading the wall and a useful place near it. The front spaces, A 1 to A 4 will be flowers, AC being edged with sweet herbs for the kitchen—thyme, savory, marjoram and sage, with a patch of the stronger growing mint at the end of A 4. The borders round the house will have rosemary, lavender, hardy fuchsia and the sweet old southernwood, or lad's love, beloved of the old cottagers who had the habit of taking a sprig of it to church with the prayer book, folded round with a clean white handkerchief. Here, also, will be China roses, cabbage roses and moss roses, the sweet bergamot and edgings of thrift and white pink. The arbour, with a seat around the three sides, will come well and make a good finish to the path that passes between B 3 and B 4. It will have ten upright posts and just enough crosspieces to guide the rambling roses and

THE SITE FOR WHICH THE ACCOMPANYING PLAN IS DESIGNED.



Digitized by Google

early Dutch honeysuckle and virginia creepers that will form the roof. The dividing hedge stops nearly level with the north-west angle of the cottage, but as it is desirable that the flower border B 4 shall be screened from the kitchen garden, it will be continued for a few yards, where shown by lighter hatching, by planting guelder rose and ribes—two shrubs which answer admirably for the making of such a shrub hedge.

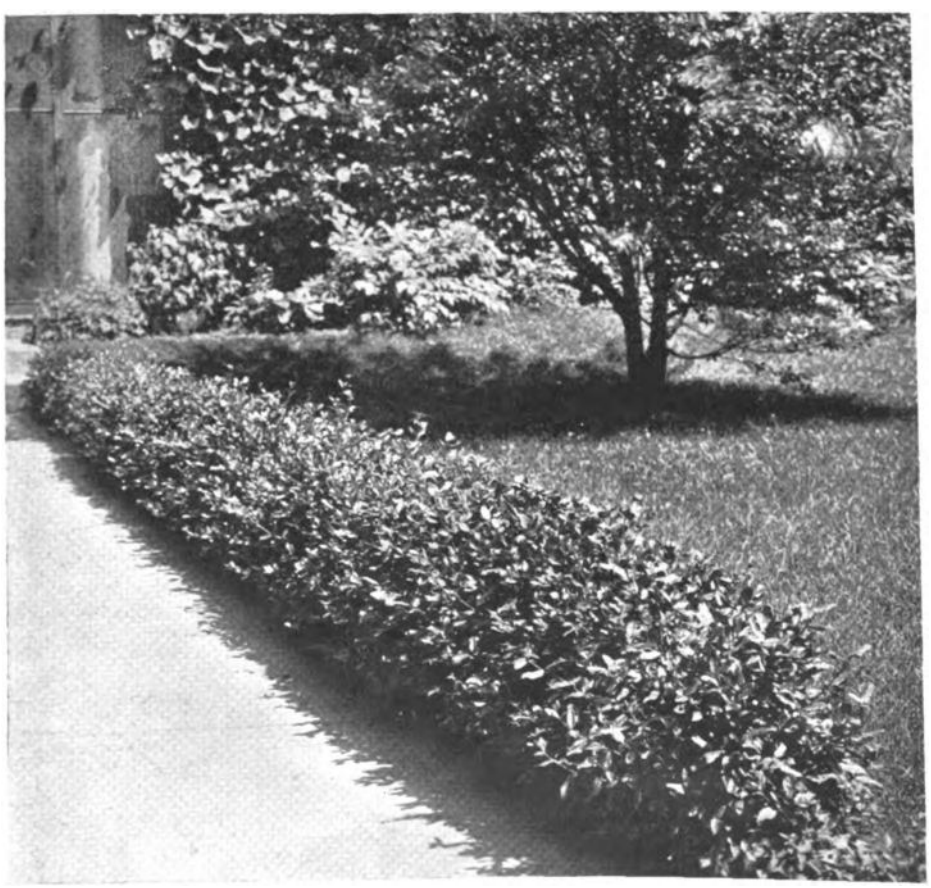
The main flower borders, C and B 4 will have all the best of the old border flowers: hollyhocks, irises, white and orange lilies, bellflowers, peonies, day lilies, Michaelmas daisies, lupins, cranesbills, phlox, lychnis, sunflowers, spiderwort and tall poppies; with crown anemones, pinks, pansies and thrift close to the path.

A small plan such as this is much the better for having some quite distinct feature. This will be given by the alley of cobnuts that carries on the line of the main path and ends in a well built summerhouse. In time the nuts will arch over and meet; meanwhile the shady path will be a delightful retreat in summer and the borders between the nuts and the path will be an exactly suitable place for a number of the spring flowers—daffodils, primroses, forget-me-nots and the Lent hellebores. These all flower before the nuts are fully in leaf; the hellebores begin quite early in March, and there is a succession of bloom till the middle of May. There will also be the old purple bulbous fumitory, seldom seen except in cottage gardens, and the pretty, quiet pink dog-tooth violet, and one of the garden forms of the wood anemone. These will all enjoy the sun of early spring and be thankful later for the shade of the nuts. At the back of the summerhouse there should be some elders; these handsome small native trees are seldom planted in gardens, though they are good both for flower and foliage, but from their usual association with farm buildings they are well in keeping with the scheme of the cottage garden.

THE PROBLEM OF THE HEDGE

A section of gardening that presents many difficulties to the amateur. As a hedge is a permanency, readers realise the difficulty of selecting suitable plants, and this article, giving a list of suitable hedge forming plants, may prove helpful to many.

WHEN planning the hedge it is important to bear in mind the purpose which one has in view. The hedge may be there to act as a boundary fence; on the other hand, it may be intended to screen some palings, or to divide one portion of the garden from another. Then, again, in the exposed garden a hedge may be set simply to give shelter to other plants that it is wished to grow. Where the hedge is to be used as a boundary fence there are no better subjects than whitethorn, beech and hornbeam. These, if planted when young and afterwards properly trimmed, will form a hedge that is practically impassable. The myrobalan or cherry plum (Prunus cerasifera) is sometimes used with good effect. When established this plant forms a hedge that is practically impenetrable, and it is very attractive in flower. In most localities hornbeam grows quickly and, with proper trimming, the hedge will not be thin at the bottom. A mixture of whitethorn and beech forms perhaps the thickest and most serviceable hedge. If this is cut in each year it will last for a very long while without becoming thin at the base. Where the hedge is employed to screen a fence, such subjects as box, privet, cherry laurel, thuya, Cupressus Lawsoniana, holly, New Zealand daisy bush (Olearia Haasti) and Cotoneaster Simsoni may be employed. The variegated forms of some of these shrubs, especially the kinds described as "golden," are extremely beautiful. The best effects are secured by mixing the varieties. For instance, a golden or green privet hedge will prove to be very attractive throughout the greater part of the year. Where the winters are not too severe, bay, laurustinus and fuchsia may be used, all with good effects. For the provision of shelter, hornbeam and yew are to be strongly recommended. Although deciduous, the hornbeam carries many of its old leaves until these are pushed off by the spring growth and so form an almost perfect wind screen. Probably the quickest shelter hedge is secured by planting a row of Lombardy poplars. These are headed off when they reach the required height, and will rapidly give a large measure of protection from rough winds. In very exposed situations it is often worth while planting the poplars to provide temporary shelter while the permanent hedge is growing.



ONE OF THE BEST PLANTS FOR FORMING A NEAT MINIATURE HEDGE OR EDGING IS EUONYMUS RADICANS OR ONE OF ITS VARIEGATED VARIETIES.

Miniature Hedges.

Miniature hedges are sometimes employed as permanent edgings to the flower borders. Of course, the old-fashioned box edging is nothing more than a hedge in miniature. A much prettier effect is secured by using Euonymus radicans and its varieties. Once the writer formed a very neat miniature hedge with baby oaks. Many seedling oak trees were collected and these were planted a few inches apart along the edge of a border. The tiny oaks were kept to the height of about 8ins., and they developed a very dense growth which was green in summer and, owing to the manner in which the dead leaves were retained, brown in winter.

The Importance of Preparing the Ground.

Seeing that hedge plants have to be on the ground for many years, the position selected should be well dressed with manure and trenched prior to planting. It is very important in setting a hedge that all the plants should be of about the same strength, so that they may all come away together and develop a uniform growth. It is sometimes, in the case of a boundary hedge, desirable to raise the actual site a foot or so, and in such cases a ditch may be dug on the outer side. Planting in double rows is to be recommended, and this is done so that the plants in one row alternate with those in the other. Where there is only a single row the plants should be a foot apart; in the case of a double row 18ins., and alternating, may be allowed. With a boundary hedge a wooden paling or a light strained wire fence will usually be required for three or four years after planting. At the end of this time most hedges will have formed a sufficiently thick growth to protect themselves.

In the fall of the year any existing hedges should be examined. Where there are very serious gaps it is worth while grubbing out the roots at the poor sections in the hedge and setting new plants. The new specimens should be as nearly as possible of the same height as the rest of the hedge. S. L. B.

THE BUSY MAN'S PAGE

Bush Fruit for the Small Garden.

FRUIT trees of all kinds can be planted within the next few weeks. Here is a selection of bush fruit which would form a suitable collection for the small garden. All the varieties, if given fair treatment, bear regular crops of good quality fruit.

CURRANTS :

BLACK.—*Baldwin, crops regularly ; Boskoop Giant, a large fruiting variety.*

RED.—*Comet, an early variety ; Raby Castle, a brightly coloured and late currant.*

WHITE.—*White Versailles, berries large, excellent cropper.*

GOOSEBERRIES :

RED.—*Lancashire Lad and Crown Bob, both varieties which resist goosberry mildew considerably.*

GREEN.—*Keepsake, early ; Langley Green, late ; two good flavoured varieties.*

YELLOW.—*Early Sulphur and Gunner, with roundish, oblong berries.*

RASPBERRIES :

SUMMER FRUITING.—*Hornet, a vigorous grower ; Superlative, heavy cropper, good flavour ; Lloyd George, almost perpetual fruiting.*

AUTUMN FRUITING.—*November Abundance, produces heavy crops of fine flavoured fruit ; Hailsham, bears fruit of enormous size, an excellent variety.*

STRAWBERRIES.—*Royal Sovereign, an early, free bearing variety ; The Duke, also fruits early, the flesh is firm and the flavour excellent ; Sir Joseph Paxton, one of the best main crop varieties, healthy and vigorous ; Laxton's Latest of All, a late large-fruiting variety.*

Labelling of Fruit Trees.

OPINIONS of gardeners vary as to the necessity of labelling. They are divided mainly into two camps—those who label everything and those who label nothing. To whichever camp readers of THE GARDEN belong, we would like to impress upon them the importance of labelling fruit trees. The amount of fruit that is sent to this office for naming is extraordinary ; indeed, we know from experience that even gardeners who may label their alpines or shrubs, consider that labelling fruit trees is a waste of time. That is not the case. Time and again readers may want to grow an apple or a pear similar to one that already crops magnificently with them. They often have no idea what the name of the fruit tree may be and so they write to THE GARDEN in desperation. Although it is usually possible to give the correct name from the fruit, yet there are occasions when a certain amount of doubt exists.

Autumn Manuring.

SOIL is frequently manured in autumn, the manure being dug in and left to form humus, the "goodness" of the manure permeating the ground by spring. A raw, fresh manure is distinctly good ; not only does the decomposition of such keep the soil warm, but decay reduces the bulk considerably, leaving the ground porous and sweet. Decay of all manurial matter into humus being a necessity, it stands to reason that slow-decaying matter like green leaves, freshly fallen leaves, shoddy, leather and other factory refuse, all such things in the "raw" state, should be dug in during autumn or winter, so that the process of decay may go ahead and be at least well advanced by spring. Lime, so essential also as a tonic and an indirect plant food, may be used at from ½lb. to 1lb. per square yard.

A Transplanting Tip.

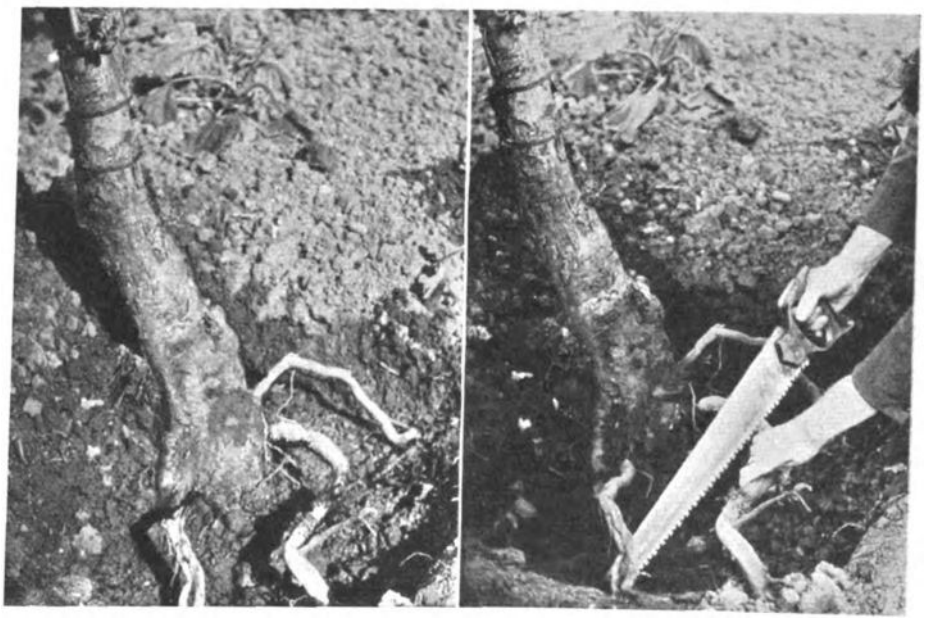
A DESIRE to shift a tree or shrub from one part of the garden often occurs, perhaps to a more suitable locality or, in the event of removal, to another garden some distance away. This cannot always be done with any guarantee of success, for under the best of care a tree will flag and die, especially in the case of evergreens, conifers, etc.

The method illustrated, however, is calculated, with ordinary care, to give very satisfactory results.

A few weeks before the time for removal, dig a trench all round the tree or shrub so as to expose the thickest roots without unduly disturbing the ball of soil or any of the fibrous roots. As a rule, when the tree is lifted the long deep roots suffer from being forcibly pulled up, and if cut often put back the progress of the tree long after it has been replanted. By exposing the roots, and severing them with a sharp knife or saw some time before the tree is removed from its original position, new fibrous rootlets which will readily take hold of the new soil are induced to be put forth around the cut.

After the roots are cut, the excavated soil is returned ; but the formation of roots will take place quicker and more surely if damp sand is placed around the cut part and a layer of leaves or rotten manure placed over before the soil is returned. It may be, in favourable weather, that the soil need not be filled in at all, rather allowing a sandy mulch that can be kept moist to take its place.

Transplanting must take place quickly. The new tender rootlets must not be unduly exposed, and, if the tree is to be carried some distance, the whole ball of roots must be bound up with damp sacking or other material.



EXCAVATE THE EARTH ON ONE SIDE OF THE TREE AND EXPOSE THE LARGE ROOTS THAT GO DOWN DEEPLY INTO THE SOIL. THOSE ROOTS THAT GROW DOWNWARDS SHOULD BE SAWN THROUGH, NEW FIBROUS ROOTS WILL THEN FORM AROUND THE CUT.

Flowers for Christmas.

LATE in October one should begin to think about the supply of flowers for the Christmas season. Roman hyacinths and other early-flowering bulbs should be well rooted by now, and these may be brought into light and warmth. Vigorous forcing in these cases is not necessary and, indeed, will often prove positively harmful to tulips and the paper-white narcissi. Such bulbs, if kept in the temperature of an ordinary living-room, will be in full beauty five or six weeks after removal from the place where they have been rooting. A few lilies of the valley are highly appreciated at Christmastime, and if one secures the retarded crowns, the culture is of the simplest. These grow best in fibre and, again, no great heat is needed. About six weeks from the actual planting of the crowns should be allowed. During the first half of this time it is best to keep the lilies of the valley in a subdued light. Any plants like primulas, cyclamen, etc., that seem heading up for bloom should be moved to positions in the greenhouse where they will get the maximum amount of sunshine. Out of doors the winter-flowering plants, like Christmas roses, Algerian irises, etc., should be given a little protection. Sheets of glass propped up on stakes will enable the flowers to develop much more finely than they would if exposed to the full effects of the weather.

Freshly Fallen Leaves.

THE leaves which are already falling plentifully from all deciduous trees are valuable gifts which the gardener can utilise in many ways. Placed in a heap in a corner where they are exposed to the weather, they rot and become leaf-mould in a year, or, in two or three years, a fine leaf-soil. Mixed directly with fresh manure as they are obtained, they increase the supplies of that valuable commodity and, practically without loss to the manure, become equally rich. Or, if placed in bags, boxes, wire netting crates or simply laid aside in heaps, they can be dug into the ground during autumn, winter or spring ; in such a case they decay slowly into a fine brown humus, one of the best forms of manurial mould. Still one more use ! They can be laid in a heap and kept moist with slops or manure wash ; they, in time, become even richer than farmyard manure and form a valuable natural manure of great value.

TALL PERENNIALS FOR PRESENT PLANTING

IT is now time to re-model or design herbaceous borders, so that all plans will be ready and planting can be carried out within the next few weeks. Planning is usually a question of personal taste, but there are certain principles upon which all mixed borders should be constructed. Besides careful colour combinations and contrasts, a well designed border should be properly graduated, and there should be a sufficient number of tall-growing perennials at the back in order to give height and character to the border. Tall plants for this purpose are plentiful, and a few of the best and most easily grown are mentioned here.

One of the earliest flowering tall herbaceous plants is the delphinium, and no border should be without this stately perennial. King of Delphiniums is one of the finest. It has large spikes of intense indigo blue flowers. Harry Smetham has rich deep blue semi-double flowers; Queen Mary is a light blue variety, 4ft. in height; Rev. E. Lascelles is a dark blue with a central white rosette. Capri is a soft sky blue; and Lamartine a true violet blue. Delphiniums are very effective when grown in circular beds by themselves.

Although lupins are known by all, many gardeners do not make the best use of them, nor do they plant the finest varieties. Some of the newer pink lupins, the rosy buffs and fawns and the clear yellow shades of the recent introductions, are great assets to the mixed border. Downer's Delight is, perhaps, the best of the carmine shaded varieties; Cross Roads is a pretty soft pink; Sunshine is the best of the yellows; Happiness a good purple variety; The Bride, a primrose lupin shaded with peach; and Saxe Blue, a variety with well formed spikes.

Coreopsis and gaillardias are both early-flowering gold-flowered perennials which bloom over a long period. Coreopsis lanceolata imbricata has clear bright yellow flowers, which are produced freely in any garden soil. The blanket flower (gaillardia) has many varieties. Ideal, Mrs. J. McKellar and The King are all good. Peonies and poppies make a brilliant show in the garden during the early summer months. Duchess de Nemours is a beautiful pure white peony; Purpurea Delasche is a deep crimson; Duchess of Teck, clear pink; and Lord Derby, a fine dark red. The Oriental poppies—Mrs. Perry, shrimp pink; Ethel Swete, soft rose; Lord Lambourne, orange scarlet; and Oriental King, crimson scarlet—should be tried.

THE LUPIN IS ONE OF THE MOST USEFUL AND EASILY GROWN OF ALL EARLY SUMMER FLOWERING PERENNIALS.

Herbaceous phloxes form another large group of perennials which will succeed practically anywhere. Frau Ant. Buchner is one of the finest whites; Elizabeth Campbell is a pretty salmon pink with a white eye; Baron von Dedem is a brilliant orange scarlet; Le Mahdi is dark violet-purple; and Comtesse de Jarnac, a variety with a large truss and variegated foliage. The bell flowers (campanulas) are graceful as well as robust in constitution. They need a sunny position in moderately rich soil. Among those which are suited for growing in a mixed border are C. lactiflora, C. latifolia and C. persicifolia and all its varieties. C. latifolia bears fine spikes of mauve, white or blue bell-shaped blooms; the bells of C. latifolia alba are pure white; while C. persicifolia alba is white, and Telham Beauty and Ryburgh Bells, both belonging to the latter class, are light blue in colour. All these grow from 3–4ft. in height.

Heleniums (sneezewort) and helianthus (sunflowers) provide innumerable gold and bronze flowers for the late summer and autumn border. Heleniums autumnale Riverton Beauty and pumilum magnificum will smother themselves with bloom. Useful sunflowers which are not coarse in habit are rigidus Miss Mellish, Monarch, and multiflorus Loddon Gold. These last few perennials are excellent for cutting. Asters are such a large class that they cannot be dealt with at all adequately here, but when sending in the plant order such varieties as Barr's Pink, Little Boy Blue, Anita Ballard, Royal Blue, Queen of Colwall and Amellus King George should not be forgotten.

Torch lilies and day lilies are becoming more popular and more widely grown. Among the torch lilies some of the finest are Orange Beauty, Corallina, Macowanii and Royal Standard. Give these a well drained position and a little protection during the winter, and they will bloom each year until October. The most suitable day-lilies for general purposes are H. flava major, Sir Michael Foster and aurantiaca. By the waterside or in the wild garden, day lilies are most attractive.

DELPHINIUMS ARE VERY EFFECTIVE WHEN MASSED IN CIRCULAR BEDS.

THE MIXED BORDER

SOME OF ITS CHARMS AND ADVANTAGES

WHILE the herbaceous border will probably ever remain as one of the prides of such English gardens as appertain to those whom John Parkinson referred to as "Gentlemen of the better sort and quality," a great many of us have to be content with something less ambitious. But if that implies necessity and suggests that the herbaceous border reigns as a sort of gorgeously-apparalled Dives over other borders, my meaning is obscured. There are hosts of gardeners, it is true, who, from reasons of economy alone, cannot indulge in the orthodox herbaceous border, but there are as many, perhaps more, who do not wish to. It is these who find in the mixed border not a poor makeshift for the more opulent affair, but a border that makes its most pronounced appeal by reason of the fact that it is always interesting at any season of the year.

A mixed border may not cost less to stock than one of herbaceous perennials. That is a matter to be decided by individual ambition and taste. But it is always more permanent and the initial outlay covers a number of years instead of only one or two. It should never need the periodical digging-up and replanting which the other demands, for once it is furnished with suitable subjects most of these will, as suggested, go on indefinitely. In this respect, as in others, a border of the kind in view is a whole garden in itself, so that the older it grows the more beautiful will it become. Replacements will occasionally be necessary, here and there a plant may have to be divided. But its primary features will remain to mature under the hand of Time, the only influence which has ever been of any real avail in fostering that ripe and mellow sweetness which is the abiding charm of the best of our old English gardens. And yet, with all this, it is the mixed border above all others which enables us to treat each plant as an individual rather than as one of the many, and for that reason alone it deserves our fullest recognition and approbation.

Informality must be the keynote of a mixed border. At the same time some discretion must be exercised in seeing that sun-loving things are not put in the shade and *vice-versa*. Mistakes will always be made (I am continually undoing mine !), for one never quite knows what dimensions a shrub or plant will attain until tried, or how it will do in this spot or the other. Then there are some aggressive, pushful, bullying subjects which will have to be considered on their merits no less carefully than the sly and insidious which may work untold trouble when least expected. Nor must a sense of fitness and proportion go unobserved in selecting one's subjects. Few things are worse than a bush or plant which is too big for its accommodation, few things more heartrending than the necessity of having to cut down or remove at great risk of loss, a shrub which, having attained maturity, has grown out of all reasonable proportions with its neighbours. As for the blending of harmonious colours, or avoidance of discordant tones, this is not a matter of much concern here, for a mixed border is not, as a well known nursery catalogue puts it, "the Burlington Arcade in the Tie-Season." The planter of discretion will not invite Tropæolum speciosum to ascend a bush of Fuchsia globosa or harass his vision by the spectacle of Geranium armenum in mortal combat with a scarlet gladiolus.

Shrubs, both evergreen and deciduous, will generally make the best basis to work upon in making a mixed border. These should, for the most part, be flowering kinds and so selected that one may get something always in bloom throughout the year, an achievement by no means difficult. One or two thin-habited tall shrubs, or small trees, such as Cotoneaster Dielsiana or Styrax Wilsoni, will always make a delightful break in contour and afford light shade for such plants as appreciate it. Then there are roses, my own choice for the mixed border being a limited number of polyanthas, which are dwarf and neat and flower all summer, and such species as R. Moyesii, R. Hugonis, R. alpina and a few selected briars of the Penzance and Austrian class. But, in these, as with other subjects, every one will follow his own fancy.

The heaths are invaluable in a mixed border, for in foliage and flower they always strike a fresh and attractive note of contrast and one may get varieties that will bloom at any season from January to December. In their own way such sub-shrubby subjects as the romneyas and Lavatera Olbia are not less effective, and when we come to herbaceous things the planter will again have to follow his own inclinations in making his choice. Personally, I have a strong bias in favour of those which are out of the common and which are more or less permanent, improving rather than deteriorating as the seasons pass. Then a mention, however, brief, must be made of the early bulbs which, round about the shrubs, will do so much to cheer us through the tarrying winter with their glad news of spring. Nor need our mixed border be without its wood anemones and their alpine sisters, its hepaticas and hardy cyclamens, its primulas and saxifrages, liliums and irises, kniphofias and alliums, spiræas, gentians and verbascums, to name but a very few of the widely differing classes of plants which will help to endow the mixed border with that unfailing interest throughout the year which is its abiding charm. A. T. J.

WHAT OUR READERS SAY

BELLADONNA LILIES.

SIR,—Accounts from all parts of the kingdom, at any rate as far north as North Yorkshire, speak of the extraordinary amount of bloom on the bulbs of the lovely Amaryllis Belladonna this autumn. Surely there must be some special reason for it. Hitherto it has been considered that a hot summer, especially a hot June, was the predisposing cause, or that a mild winter caused strong and early growth and ripening. Such was not the case this season at any rate. The summer did not even begin till July was well "in," and the ground was exceptionally cold until late in July, so some other cause must be sought. The answer, I think, can be found in the actinic power of the sun this year, and I hope astronomers may be found to corroborate this statement. How much the absence of smoke may have helped I dare not say, but I remarked on the east and north-east coast of England that the actinic power of the sun's rays was most exceptional, so much so that I looked out for the effect it might have, and the result, I think, justifies these remarks. Others, I hope, may add their observations.—EDWARD H. WOODALL.

THE LORETTE SYSTEM OF PRUNING.

SIR,—I see in THE GARDEN for October 2nd that "G. C. O." wishes to get together some notes about the Lorette system of pruning. The following may therefore be of interest and use to him :

To convert all shoots into fruit-forming spurs is the chief attempt of the Lorette system of pruning. So, in trying this method the shoots are cut when the sap is moving, and not when the tree is dormant, as is the usual practice.

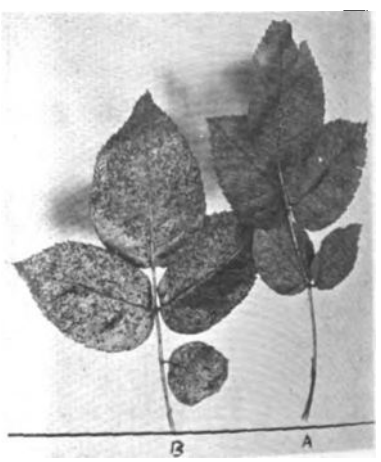
The best time to start this method of pruning is in the spring—April, May and June, but it may also be carried out in July, August and September.

In dealing with apples and pears, pruning will be done at different times, the apple receiving attention later than the pear.—BRYCE WILSON, *Durham*.

ROSE RUST.

SIR,—Rose rust (Phragmidium disciflorum) has been very common this summer, in some cases turning every leaf bright yellow underneath. This disease is one of the many rusts that attack plants, but, unlike the rusts that attack wheat and barberry, all the stages are on the one plant, in this instance the rose.

In the case of this rust, the most destructive stage is formed by the æcidial spores. These produce large bright orange lesions or injuries on the branches, petioles, and occasionally



THE TWO STAGES OF THE RED RUST DISEASE. THE SPRING AND WINTER SPORES.

on the buds and fruits. These orange spore-beds are sometimes nearly an inch long. They cause a good deal of distortion and swelling on the branches or other parts of the plant tissue. This is the most infectious stage. The myriads of spores alighting on fresh rose bushes start subsidiary infection. The next stage is small, round, pale orange spots on the underside of the leaf, little round lumps of the uredo spores. Finally, a black spore, the teleuto spore, appears on the underside of the leaf also, in little dots of an intense black. These can pass the winter on the dead leaves. In the spring, the black spore produces another smaller spore, that again infects the rose, or other roses, producing the yellow lesions of the æcidial stage.

The fungus also over-winters by means of a resting mycelium. The fungal threads can remain dormant in the plant tissue where the orange spots were, on the stem, etc., and again awake to activity in the spring and throw up quantities of the yellow æcidial spore. If the infection is only a leaf infection, the control is much simplified.

Control has to be based on these two facts, the teleuto-spore stage on the dead leaves

Digitized by Google

and the resting mycelium in the twigs. This resting mycelium is localised, not general.

All dead leaves should be collected and burnt in the autumn. At the present time all infected parts should be cut out, taking especial care to cut out any infection on the twigs and branches. These also must be burnt. If infected leaves or twigs are thrown on a rubbish heap, the spores can blow about and start another infection.

In case of any overlooked source of infection, the bushes should be sprayed with lime sulphur early in the spring (lime sulphur 1 gallon, water 49 gallons). The disease does not remain in the soil, and can only live in the tissues of a rose plant. It may occur on the wild rose. Dutch roses are rather often attacked.—N. L. ALCOCK.

GLADIOLUS LANGPRIM.

SIR,—We feel sure that it will be of interest to put on record, once for all, the origin of the hybrids resulting from crossing the species Gladiolus primulinus with large-flowered hybrid gladioli (G. gandavensis).

Sir Francis Fox sent us, and to the Royal Kew Gardens, in the year 1905, the first corms of G. primulinus, which were introduced into Europe. Mr. Townsend, who was in charge of the building of the Zambesi bridge in 1903, had collected these bulbs and had sent them to Sir Francis Fox, a partner in the firm which was building the bridge. Our Mr. James Kelway handed them at once to Mr. Field, the foreman of our gladiolus department, with instructions to grow them inside until the hardiness was known, and then ouside, and to cross them as soon as possible with the best varieties of the large-flowered section, the descendants of Souchet's varieties, which sprang from G. gandavensis. In 1922 the *Times* published a statement that the Dutch and American nurserymen were responsible for the production of this beautiful new race of gladioli. We wrote to the *Times* contradicting this, but the letter was not inserted. We then wrote to Sir Francis Fox, who, in his reply, substantiated the facts we give above, and added, "I do not think the Dutch growers had any for some years after. I regard you as having produced the earliest and most beautiful results." Messrs. Lemoine, the well known French raisers, raised a cross between G. primulinus and one of their Lemoinei section. We have seen these varieties, which are very similar to the well known Lemoinei hybrids in shape and, as well as very much smaller, are quite distinct from the section now so popular.

The corms sent to us by Sir Francis Fox in 1905, flowered in 1906 and were hybridised and used for hybridising. In 1912 the Royal Horticultural Society gave us an Award of Merit and their Silver Floral medal for our exhibit of flowers from the strain, and the National Gladiolus Society at the same show an Award of Merit for the hybrid variety which we had named Golden Girl.

The first hybrid varieties of this section which were ever catalogued were our Golden Girl, Ella Kelway, Josephine Kelway, Ralph, Friendship, Banshee and Elf. All these were offered to the public in 1913.

During the war, work on this new gladiolus naturally ebbed in the countries which were at war. Holland and America were able to go ahead with such material as they had, but we should like it known that it is due to Sir Francis Fox's kindness in sending us the species, and to our Mr. James Kelway, who supervised the work of crossing, that the credit of the inauguration of this now popular flower is due. The press in 1912 suggested that some special name be put to these gladioli, and we distributed them under the name of Gladiolus Langprim, Lang for Langport, Prim for primulinus.—KELWAY AND SON.

ASTER FARRERI.

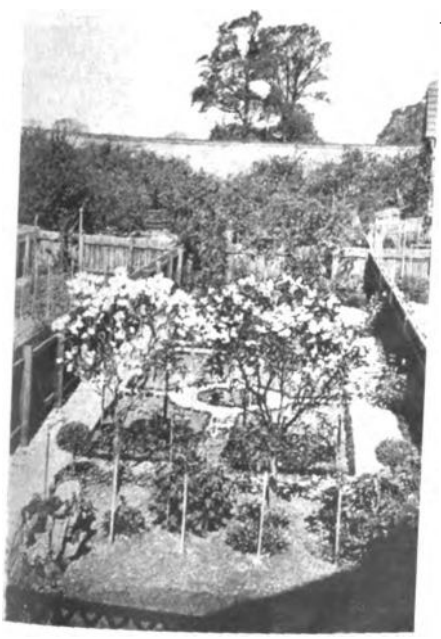
SIR,—I should be glad to learn from readers who have grown the fine Aster Farreri their experience of its character as a flowering plant in gardens. Here it flowers fairly well in dry soil close to a stone edging to a flower border. But I have learned from others, not only from those who have cultivated it themselves, but who have seen it in several other gardens, that it seldom flowers with them. According to Farrer, it appears to grow in grass and never on the high ridges. —S. ARNOTT, *Dumfries*.

AN INTERESTING PLANT.

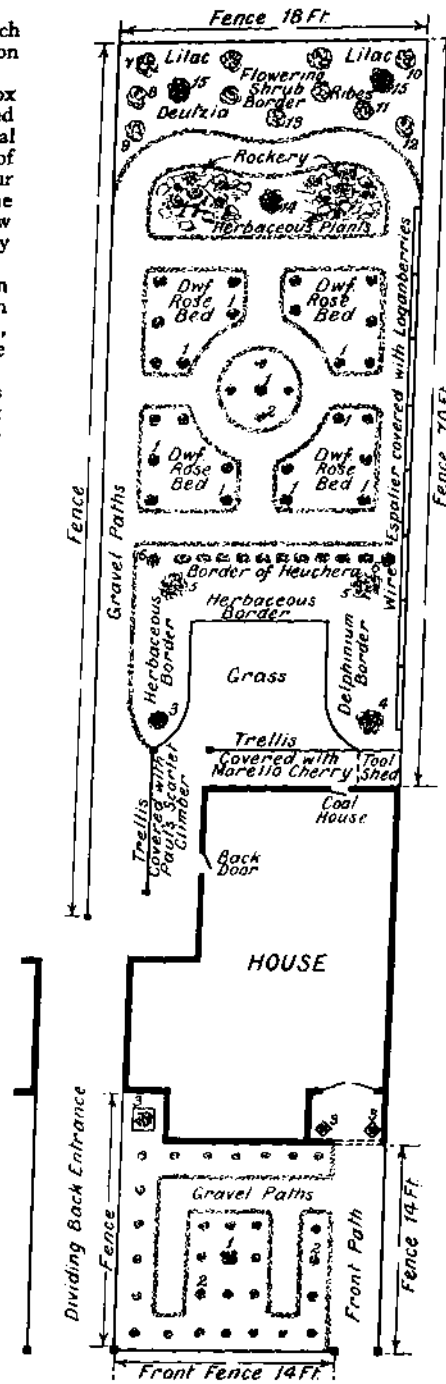
SIR,—I have some plants of what is known as "The Tree of Life," the culture of which is rather unusual, so a note on it might interest other readers. My employer sent me four leaves of this plant while on a visit to Bermuda and West Indies. I understand hedges of it grow out there. The leaves resemble the cacti tribe, and are fleshy and serrated. I was instructed to tie a piece of thread to the stem of each leaf and hang them up in the plant houses, when the young plants would grow from them. The leaves were hung up in different houses in March, and I found they started best in a heated pit, where young plants commenced growth in a month in a temperature of 60° or rather more. The leaves only got water on them with the syringing down of the pit. I cut out small plants from the leaf with a knife and put them into a box of compost of sifted leaves. After plants got away in growth I put them into 3in. pots with a compost of 2 parts loam to 1 part leaf-mould and sand, not in too fine a state. I now have plants in 5in. pots, and they are over a foot in height, and look fine and healthy. I started to feed with weak soot water and an occasional watering of liquid manure not too strong. I noticed the first break of leaves on stem were single, but have now increased to set of five leaves on top. I am informed the plant has a blue flower. I would be grateful if any reader can give me history of this plant together with the botanical name and proper culture, as I have just had to experiment in the latter case.—W. J. B.

THE JOY OF MAKING A NEW GARDEN.

SIR,—I have read with interest the articles by Miss Jekyll appearing in your valuable paper THE GARDEN, but I notice that up to the present all the proposed plans have been for gardens of fair dimensions. As you are aware there are hundreds of thousands of houses in this country the gardens to which, although varying in depth, are, in width, limited to the frontage of the houses. My own house is in this category, and I thought the enclosed plan and photograph may, perhaps, interest your readers, showing as they do what *can* be done with these small pieces of ground with very little trouble and small outlay. I would add that six months previous to the photograph being taken the ground—back and front—where not rough pasture was the builders' dump.—G. WYATT, *Huntingdon*.



A CHARMING GARDEN IN A SMALL SPACE.



The numbers refer to those given in the accompanying plan:
1.—*Standard roses*; 2.—*Dwarf roses*; 3.—*Pyramid box in tubs on stone slabs*; 4.—*Cupressus macrocarpa lutea*; 5.—*Standard lilac*; 6.—*Short standard bay trees*; 7.—*Berberis Darwinii*; 8.—*Ceratostigma*; 9.—*Berberis vulgaris*; 10.—*Berberis Wilsonæ*; 11.—*Viburnum Carlesii*; 12.—*Lavender*; 13.—*Dipelta floribunda*; 14.—*Standard Prunus*; 15.—*Standard Pyrus*.

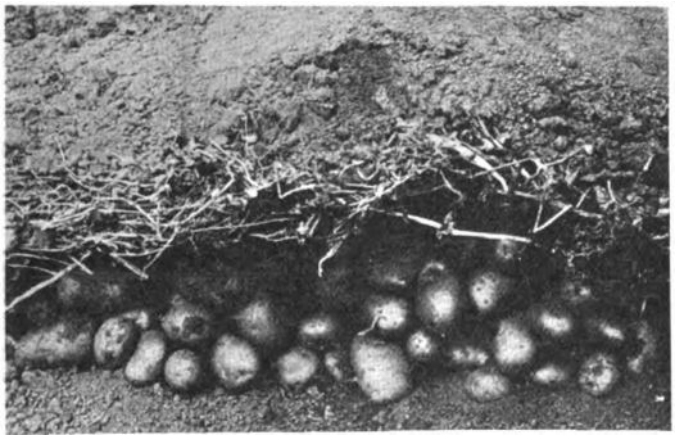
THE FRUIT AND KITCHEN GARDEN

Storing Potatoes.

THE clamp is undoubtedly the very best method of storing potatoes. The fact that the clamp is the usual means employed in the fields is no criterion that it is suited to the garden, for it has the advantage of being well in the open and on a large scale, and the loss of a few tubers here and there does not affect the value of the whole.

This is quite different with the gardener—he wants every one of his potatoes to keep sound until he is ready to use them; and it pays him, first, to make a really efficient clamp, and then, to store only sound and good-sized tubers.

A good, hard well drained bottom is needed on which to lay the tubers, to start with; next, the tubers themselves should be thoroughly dry before being placed in the clamp, and should be packed loosely in a triangular heap. As with everything else, a certain amount of air circulating between the potatoes is necessary. See that the layer of straw is perfectly dry and clean and quite free from anything that would decay. Potato haulm, if thoroughly dried in the sun, may be placed on top of the straw layer, and the earth that follows is best well pulverised



A POTATO CLAMP.
Showing a firm dry bottom, the tubers lying loosely, and the covering layers.

before being placed on top. This, again, ensures airiness without exposure and drainage without becoming unduly dry. Such a clamp never gets sodden in heavy rains and every drop of surplus water quickly finds its way to the lower level, where a further means of escape into the subsoil awaits it. The potatoes therein lie in an atmosphere that discourages and prevents decay, the premature formation of sprouts, and keeps the tubers in an eatable condition.

Never clamp a damaged potato or one that shows any sign of disease; it is better to put cut or damaged tubers in a small separate clamp for early use, rather than mix them with the sound potatoes.

A Simple Way to Enrich Poor Soils.

VEGETABLES are very hungry plants. To be successful with them their larder must be well stocked to begin with and, as required, replenished from time to time. The present is a good time to see about stocking the larder—the soil. As the leaves fall from the deciduous trees and shrubs, collect them and place all in a heap in a part of the garden where they can be dealt with by wetting and turning occasionally. As the heap is turned a sprinkling of common salt will help to keep them moist and thus hasten decay. All the leaves from the vegetable quarters and grass cut from the lawn and any banks should be treated in a similar way. After a few turnings some common garden soil should be added to the heaps, and if seaweed can be procured mix some of it with any strawy litter in hand. The seaweed will help to rot such litter sooner than any other material. As the work of digging proceeds put in some of this prepared manure at the rate of three barrowloads per square rod for all kinds of vegetables except root crops. For the benefit of the latter well rotted manure must be dug in or, better still, ground devoted to them next year that has been heavily manured this past summer for such crops as potatoes, celery and leeks.

Forcing and Propagating Seakale.

OCTOBER is a suitable time to commence lifting a few plants of this useful vegetable for forcing. The crowns may be left lying exposed on the ground for a few days, as they force better if they have been slightly frosted. Nothing is easier to force than seakale, all that is necessary being absolute darkness, and a temperature that never rises above 60° Fahr. It is well to begin with a temperature of 45° Fahr. and rise no higher than 55°. Later supplies are obtainable by inverting large pots over the roots in the open ground and heaping them around with hot manure or leaves. The space under the stages in greenhouses may be successfully used for forcing purposes, providing the front is covered in such a way as to exclude all light. Pack the roots fairly close together and work light soil between them. Water with a rose can when completed and afterwards as required. A fresh supply of roots should be put in each week to ensure a constant supply. In November a good batch of roots may be lifted, and after being exposed to frost they should be stood together and covered with a good layer of leaves, so that they are accessible in frosty weather.

Seakale can be easily raised from seed, but the quickest and best way is to procure some good "thongs" or root cuttings from a reliable source. These should be taken off the plants when they are lifted for forcing. They may be cut 1in. below the crown and should be 4ins. or 5ins. in length and as thick as a man's little finger. The thickest end will form the crown and should be cut straight across, but the lower end should be cut on the slant. Lay them in sand until March, when they may be planted on a deeply dug, well manured and exposed piece of ground. Plant in rows 2½ft. apart and 18ins. between the plants in the rows. Previous to planting, rub off all the buds except one at the crown. Promote growth by all possible means during the summer. Crowns that have been lifted and forced in heat are of no further value, but those that have been blanched outside by placing a seakale pot over them may be forced in this way for many years. It is one of the most useful of our vegetables.

Early Rhubarb.

AN early crop of rhubarb may be secured if a few roots are lifted, within the next few weeks and exposed on the surface for a few days. If during the period there are slight frosts at night, this will be an advantage; should the weather be very severe, protect the uprooted clumps with matting, dry fern or even newspapers. Afterwards the roots may be arranged on the floor of a shed, cellar or, better still, in a mushroom-house or structure where there is warmth. The interstices between the roots should be filled with light rich soil. If the roots are in a place where it is not dark, they should be covered with boxes, tubs or pots. Keep the soil rather moist, the actual amount of water varying according to the degree of heat in which the rhubarb is grown.

A Horse Radish Bed.

HORSE RADISH is so useful for culinary purposes that it is worth while devoting a small bed to its culture. Almost any situation which is not heavily shaded by trees and shrubs will suit the plant well. The soil should be fairly light, not only because this meets the needs of the horse radish best, but also on account of the fact that it is very difficult to dig up the roots on stiff ground. The best time for planting horse radish is from the end of October to March. In making new plantations the crowns may be planted a foot deep with a crowbar. Another way is to insert long, straight pieces of the roots, putting them in rows about 9ins. apart. Before planting, all small fibrous roots should be rubbed away: as long, straight stems without forks are the best. Never allow horse radish to stray into adjoining borders, as it will prove a most difficult plant to eradicate.

How to Treat Unfruitful Apple Trees.

UNFRUITFUL apple trees may sometimes be made fruitful by means of root pruning, especially if the trees show a tendency to run to wood. A trench cut at about 4ft. from the stem or trunk of the tree, and for about half way round, may be dug in the autumn or winter months, and the thick, descending roots cut off with a sharp knife or axe.

Leave the fibrous roots intact and take care not to bruise or break them, nor unduly expose them to the air.

Some apple trees may prove unfruitful owing to a lack of cross fertilisation. Single trees are frequently barren from this cause. The remedy is obvious. Obtain some pollen from apple blossoms on trees elsewhere. Use a camel hair brush to collect the pollen and to transfer it to the non-fruitful blossoms.

Cut off any blossoms that are beginning to fade, or are not quite in full bloom. Treated thus, the unfruitful trees may be made to yield a good crop of fruit, and to continue fruitful for many years afterwards.

A Select List of Fruit Trees for a Small Garden.

IN a small garden it is not possible to grow many trees of numerous kinds. The only way to include quite a large number for the space available is to plant, mainly, cordons. The next best plan is to prefer bushes, standards being the worst form of tree. The following list includes some of the best for amateurs starting a new garden; of course, few or many may be planted according to the size of the garden. *Apples, dessert:* Beauty of Bath, Lady Sudeley, James Grieve, King of the Pippins, Cox's

Digitized by Google

Orange Pippin and Allington Pippin. *Cooking:* Golden Spire, Stirling Castle, Lord Derby, Lane's Prince Albert, Newton Wonder, and Bramley's Seedling. *Pears:* Durondeau, Doyenne du Comice, Emile d'Heyst, and Williams' Bon Chrétien. *Plums:* Victoria, Jefferson Gage, River's Czar, Belle de Louvain, Kirke's Blue, Green Gage and Pond's Seedling for a very large fruit. *Cherries:* May Duke, Knight's Early Black, Bedford Prolific, Governor Wood and Morello. *Gooseberries:* Keen's Seedling, Leader, Speedwell, Rifleman, Telegraph, Whitesmith, Keepsake, Whinham's Industry and Crown Bob. *Currants, red:* New Red Dutch, Fay's Prolific and Raby Castle. *White:* Dutch, Transparent and White Versailles. *Black:* Baldwin's Champion and Black Grape. *Berries:* The British blackberry, the loganberry. *Fig:* Brown Turkey. *Grape:* Black Cluster, quite the best. *Medlar:* Nottingham. *Nuts:* Kentish Cob. The fruit trees should occupy parts of the garden where they will get the maximum amount of sunshine and not obstruct it from other crops much. Do not overcrowd; it is better to be content with fewer trees.

Weeds.

REMEMBER that weeds grow apace at this time of the year, and it is imperative that they should not be allowed to come to maturity. A head-gardener once told his outside assistants to pull up weeds or otherwise destroy them any time between special work that he had instructed them to do, rather than waste time, if he was not there at the moment to set them to do some other kind of work. We may all, in our own gardens, bear this in mind, and, during odd moments, set about the work of weed destruction. It is wonderful how clean we may keep our gardens if we, having ten minutes to spare, take the Dutch hoe, for instance, and hoe up the seedling weeds in the kitchen garden, under the gooseberry, raspberry or currant bushes or between the rows of winter greens. Every time the hoe is pushed about 1in. below the surface of the soil, perhaps three or four hundred weeds are killed. Then it may be that five minutes devoted to the pulling up of tap-rooted weeds, such as docks and dandelions, will prevent the seeding and spread of the pests to other quarters. Dry weather for hoeing and wet weather for hand-weeding should be the rule. Burn all seeding weeds found, then there will be an end to them all.

HINTS WORTH REMEMBERING

This is a further instalment of Hints that have been received from our readers in response to our request. There seems little doubt, judging from the numbers that have reached us, that this will prove a most useful feature of THE GARDEN *in future. We hope, therefore, that all our readers will assist to make this page as valuable as possible by sending in their Hints, the result of personal observation and trial, and so help the gardening public in general. Hints which will be specially considered as worthy of a prize will be those that are seasonable as well as interesting and apply particularly to duties that can be carried out in the garden at the present time.*

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Each must be sent in on a separate sheet and must not be more than 300 words in length.

THE HALF-GUINEA HINT

A Substitute Fuel for the Small Greenhouse.

The husks of beech nuts are falling fast now, and if these are gathered before the leaves fall and are stored in the dry will be useful as fuel later on. As we shall probably not be able to obtain fuel in any quantity for some time, the above will be found useful, especially if mixed with a small amount of coke or small coal.

I have already gathered three or four large barrowfuls, and hope to get some more. They burn well, emit a good heat and stoke easily with a shovel.—H. F.

Hints on Planting Shrubs.

If you intend to plant this autumn, or in early spring, any of the following shrubs, plant them direct from pots. Insist on pots when ordering; it is courting failure to plant daphnes, cistus, fancy brooms and some ceanothus taken direct from nursery lines. Ensure success with chimonanthus, chionanthus, eucryphias, enkianthus, osmanthus, Viburnum Carlesii, by following the same lines.—W. G.

Propagation of Campanula pyramidalis.

When removing old flowering plants of Campanula pyramidalis during October, cut away from each plant a few thick, long, fleshy roots. Cut transversely the thickest ends, trimming off the tapering ends in a slanting direction, to a length of 3ins. to 4ins.—*i.e.*, treat roots similarly to seakale thongs. Insert prepared roots in boxes of sandy soil. Keep in cold frame until March, when each root will have developed to a sturdy plant of four or more separate growths. Transplant each plant to border where intended to flower, or pot on for greenhouse flowering. If the above method is adopted annually, it will provide the border with its tall, graceful spikes of blue and white flowers during the months of June and July. I have proved that where roots are so treated better shaped plants are obtained. Every root produces an established plant. It is a quicker and more convenient way than seed sowing.—C. H.

Tying Raspberry Canes to Wires.

What a tedious job this is when one ties each cane separately. The following method, which I tried with great success last year, will be found to save hours of work: Get a ball of thread as used by saddlers, wind this on to a small or medium sized cotton reel. Then, having fastened the thread to the post at the end of the row, you place your first cane against the wire and give the thread a twist round the cane and wire; continue on in like manner all the way up the row. It is advisable to knot your thread to the wire, say, every twenty canes, in case of the thread breaking and so running loose all the length of the row. It is equally a saving of time when cutting away the old canes the following year.—G. W. G.

Growing Chrysanthemums in Pots and the Trapping of Earwigs.

To all who grow chrysanthemums in pots, staked with canes, and are troubled with earwigs: Get a piece of putty and fill the hole at the top of the cane with the putty, pressing it down with a piece of stick to the depth of ¼in.; this will dry hard in a few days, suffocating the earwigs that are inside the cane and preventing any more from entering, as the canes are a favourite hiding-place for earwigs during the daytime. Then place a piece of broad bean stalk or artichoke stalk, about 5ins. long, on the soil at the top of the pot. Go round every morning with a can of boiling water, shaking the earwigs out of the stalk into this.

Earwigs at this time of the year do a lot of damage to the plants, eating the heart and also the buds, often destroying the whole plant.—B. R.

Retaining Sweet Scabious for a Second Year.

When clearing "summer stuff" that has done duty during the season past, think twice before removing the sweet scabious. A true garden friend, not only is it still doing its best, by thrusting out fresh flowers, to beautify any modest corner where the seed has been thrown; but it will flower the second year, with a little care, yet more finely than the first. Even through such a winter as last, some plants which had already flowered well were kept under a south wall out of doors, the snow often standing on the pots. Replanted in good soil in May, they have already been blooming for two months, and show few signs of ceasing. It seems that "biennial," like "annual," is a misnomer for this plant, which is really a short-lived perennial. The colours from which to choose, when the moment comes for saving them, are singularly beautiful. Has any reader tried the experiment of keeping them a third year?—E. S.

How to Make Your Labels Show Up Clearly.

Many suggestions have been offered about the labelling of plants, but, use which label you wish, you cannot get a more lasting or better result than by using the "New" Stephens' Outdoor Ink. I have given this ink a thorough test, and find that for wood labels which have been painted and are perfectly dry it is much better than any indelible pencil which is in use so much now.

It would be a boon to many purchasers of plants if nurserymen used this ink to write their tickets with, which they usually attach on trees or plants before despatch, for having tried this on these tickets I find it is absolutely waterproof, and it can rain on the ticket for days and you can still read your variety of plant without the fear of the ink running and smearing all the ticket. It can also be used for zinc or celluloid labels equally as well, and is used in the ordinary way with a clean pen. I suppose many nurserymen will stock it, for I purchased mine from our local nurseryman.—W. A.

Saving the Cost of Besoms.

Save handles of worn besoms, carefully removing the peg holding the twigs. Procure all elm suckers, keeping them straight, tie in round bundles very tightly, cut off thick ends, leaving the twigs 3ft. long, and stack for future use.

When brooms are required, pull the stick ends in as tight as possible with a piece of rope, fix with two pieces of wire, drive in handle, and secure all with a peg right through handle between the two wires. Different kinds of brooms can be made in this way by using thick or thin twigs from birch, elm, common broom, hazel, willow, etc. These, when well made, last out three of the bought variety.—H. M. B.

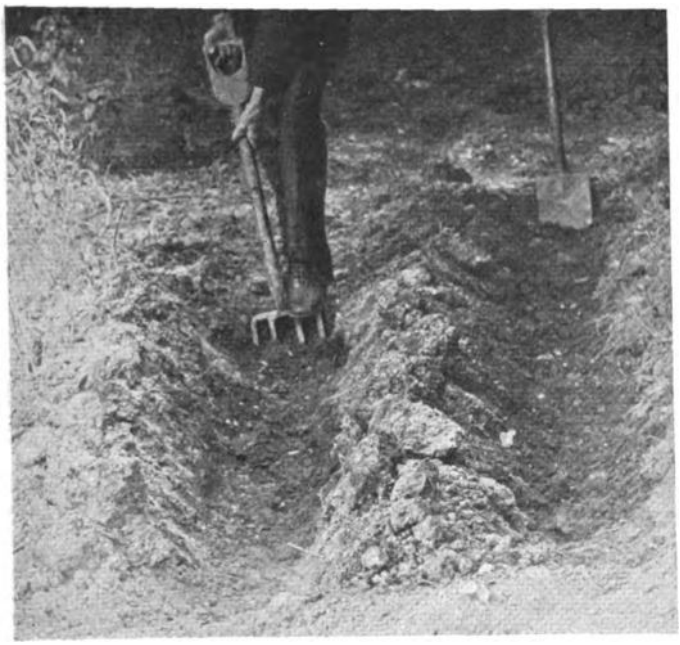
SPADEWORK: A MOST IMPORTANT GARDEN OPERATION

How to Treat Refractory Soils.

A STIFF hard clay, a chalk subsoil, and naturally wet ground are most difficult to manipulate and keep in good condition. In each case it is a question of digging the topsoil and subsoil, manuring and draining; but the labour entailed is always great and uninvitingly tedious. Here is a method that eliminates quite half the labour.



THROW UP THE SOIL IN LUMPS ON EITHER SIDE TO FORM A RIDGE.

First, fork up the ground and pile the lumps, just as they are, in a heap on either side as you proceed, thus making a ridge all along the line of digging, with a trench at the side, perhaps scattering some lime over the ridges.

Now place a layer of manure in the trench. Get into the trench and dig the bottom of it a spade deep, incorporating the manure. Leave the trench and the earth thus disposed during the remainder of the winter months.

PLACING MANURE IN THE TRENCH AND DIGGING IT IN.

In early spring it will be found an easy matter to knock these lumps to pieces and return the pulverised earth to the trench from which it was taken; and when all is level once more, go over the whole and give it a good surface digging. Here you have the very best medium for which one could wish in which to grow onions, parsnips, carrots, peas or sweet peas. The worst of soils can be made passable and even fertile by this combined action of the digger, the weather, and the length of exposure. —H. A. D.

The Soil and its Preparation for Planting Roses.

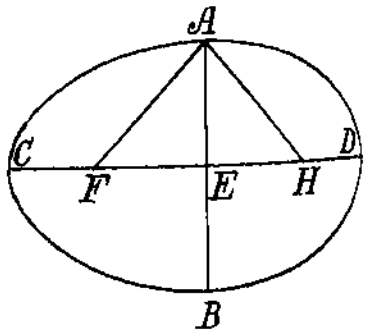
NOT only the soil, but the position in the garden must be duly considered before any roses are planted. Odd plants, of course, may be planted in various parts of the garden; and so planted often do fairly well. But we are now considering the more important question of a rose garden, or, at least, a rose border of good size. The position should be an open one sheltered from south-west winds, but not by high trees or shrubs or buildings too close to it. I will refer briefly to one rose garden that was surrounded by laurels and other kinds of shrubs and trees of laburnum, prunus and others of like growth. The garden was entered from two ways, north and south respectively, through openings in the shrubs, which formed a belt about 12ft. distant from the outside rose beds. When all the plants were young and first planted no doubt everything seemed to be all right, but later on the shrubs grew apace and produced roots in great numbers; these roots soon permeated the soil in the rose beds and robbed the plants to such extent that they barely existed. Lifting and replanting was useless, as the foreign roots were first again in the soil; feeding, too, benefited the shrubs more than the roses. The shelter plants should have been at least 30ft. distant. Where this space cannot be assured, then do away with any idea of protection from a living shelter. A somewhat greasy, rich loam—greasy when first wetted and pressed in the hand—is an ideal one for rose trees to grow in. The greasiness, however, must not emanate from any self-binding gravel that may be found 1ft. or so below the surface, as I have found such unsuitable for rose growing. A light, sandy soil is unsuitable, too, in itself, but such can be improved wonderfully by the addition of good, holding loam, which should be mixed with the top soil so that the roots will be benefited at once. A really sandy soil will not do at all by itself. Such sandy soils should be removed and replaced by good loam; this is the best way in the end.

A thorough preparation of clayey soils can only be ensured by trenching in the autumn, exposing throughout the winter to frosts while in a rough state, cropping in the summer with annuals or similar plants and then planting the roses the following November. But such patience cannot always be exercised, so we should, as an alternative, trench the ground early in the autumn.

There are cases where rose lovers have to deal with a gravelly soil—very gravelly—and the plants cannot be expected to do really well in such a rooting medium. The right thing to do is to take out the gravel, forming pits 18ins. deep and refilling with good loam. The trees are planted and, from time to time, odd soil, as it can be spared, is wheeled to the quarter and tipped on the surface, spread out thinly and allowed to remain there; more being added to it as it becomes available.—G. G.

CUTTING LAWN FLOWER BEDS.

A LAWN is often improved in appearance by putting flower-beds in it, but the removal of the turf, especially where curved edges are concerned, is not altogether relished by the amateur. The writer has found that the acutal cutting of the turf can be done just as efficiently and quickly by using a linoleum knife, costing about a shilling, as by employing a tool specially designed for the purpose.



In cutting out a circular patch first decide the centre, and drive in firmly a stout, round wooden stake. Then take a piece of cord and make two loops at the ends, one loop to hold the knife, the other to go over the stake. The loops should be quite loose to allow free movement both for the knife and around the stake. Care should be taken to see that the length of the cord, when one end is placed over the stake and the other over the knife, is equal to the radius of the circle it is desired to cut.

Holding the knife perpendicularly it will be found quite a simple matter to cut into the sod, leaving a clean, straight edge. If care is taken to keep the cord taut and horizontal and running freely in its loop around the stake, a perfect circle will result.

The cutting of an ellipse, which shape is often desirable, can be just as readily carried out if a little extra care is exercised.

Barr's Gold Medal Lupins.

BARR'S HYBRID LUPINS.

Lupins are among the most beautiful of Border Plants, maintaining a floral display from May to the end of September in a manner unequalled by any other hardy plant.

LUPINUS ARBOREUS (Tree Lupin), grand shrubby perennials for sheltered sunny positions, forming large bushes, crowded with terminal racemes of fragrant flowers, which may be gathered daily for a long time without diminishing the effect, ht. 3ft. to 5ft.

	Each s. d.
Bridesmaid, white and primrose changing to rose, fragrant	1 0
Golden Spire (Yellow Tree Lupin), fragrant golden-yellow flowers, prized for cutting, very free	1 0
Snow Queen (White Tree Lupin), beautiful pure white fragrant flowers	1 0
Sunset, yellow shaded old gold, very fragrant	2 6
Taplow Yellow, sprays 12 inches long of clear yellow flowers; the finest yellow Lupin yet raised	1

1 each of 6 beautiful Tree Lupins, 8s. 0d.

LUPINUS HYBRIDS, the result of crossing and inter-crossing **L. polyphyllus** and **L. arboreus varieties,** combining in many instances the characteristics of each parent. They are all very free-flowering and make valuable border plants. For these hybrids we have received an AWARD OF MERIT by the R.H.S. and the GOLD MEDAL OF THE NATIONAL HARDY PLANT SOCIETY. These beautiful new hybrids have been mostly raised at our Nurseries.

	Each s. d.
Captivation, soft blue and white	1 6
Chameleon, opening blue and yellow and changing to blue and white	1 0
Eastern Queen opening mauve and yellow, and passing to rosy buff and fawn	1 0
per doz. 10/6	
Kittiwake, lower petals delicate flesh pink, upper petals bright rose	2 6
Lady Constance, lower petals wistaria blue, upper petals shading to cream	2 0
Mauve Beauty, deep mauve passing to a beautiful silvery mauve	2 6

	Each. s. d.
Nelly, white tinted rosy mauve, on spikes 1½ft. to 2ft. in length, 4ft. per doz. 10/6	1 0
Primrose, delicate primrose flowers, upper petals of a deeper shade	2 6
Prince of Orange, very striking and floriferous, golden-buff shading to bright orange, fine spike	5 0
Queen of Sheba, lower petals violet, upper petals bright golden-yellow, 4 ft.	2 6
Rosy Gem, rosy mauve shot with yellow	1 0
Royal Purple, a handsome new variety	1 6
Ruby King, deep claret red, fine spike	1 6
Seraphine, mauve, shaded gold	1 6
Southern Belle, lavender and mauve, a beautiful colour combination,	1 6
Sunshine, bright golden-yellow	1 6
The Bride, soft primrose shaded delicate rosy peach, continuous bloomer,	1 0
Yellow Boy, golden yellow, upper petals of a deeper shade and passing off buff	1 6

1 each 12 beautiful Hybrid Lupins to name, 15s. 0d.; **1 each 6 beautiful Hybrid Lupins** to name, 7s. 6d.

First decide upon the length and width (the mathematician would call these the major and minor axes) the ellipse is to measure, and mark these by four pegs (A, B, C and D in the diagram). Then make two straight cuts in the turf joining AB and CD, the cuts crossing each other at the centre E. From A mark off two points F and H on CD, making the lengths AF and AH equal to CE. At the points F and H drive two stout round wooden stakes firmly into the grass. Make a loop in a cord and let the loop go loosely over the stake at F. Now stick the lino knife in the ground at A, and pass the cord from F round the knife at A, finishing the cord with another loop at H. If the knife is now taken from the ground and made to move in the angle of the cord, it will be found to describe the required curve of the ellipse.

Just a final word—it is desirable that the turf should be thoroughly damp (preferably after a heavy rain) when cutting is done to ensure a clean, sharp edge to the flower-bed.—J. W. H.

AN AUTUMN FRUIT SHOW

THE Royal Horticultural Society held on October 12th and 13th at Vincent Square a fruit show which consisted mainly of apple and pear exhibits. The show seemed to contradict the fact that this season has been a notoriously bad one for fruit, particularly apples, for the entries were surprisingly large in number and the hall was well filled with first-class fruit. Although fruit crops as a whole have been very poor in certain districts, pears must have cropped exceedingly well in some parts of the country, judging by the quantity and quality of pear exhibits which were staged.

A splendid collection, which included grapes, peaches and pears, was shown by the Duke of Newcastle. The pears exhibited were of enormous size, Pitmaston Duchess being the largest. Major F. J. B. Wingfield Digby had a smaller fruit collection. His grapes Alicante and Pear Souvenir du Congrès were both in good condition. The George Monro Memorial Cup was awarded to the Duke of Newcastle for the finest exhibit of grapes shown by an amateur. Gros Colmar was the best grown among the four varieties exhibited. Mrs. G. Tufton showed two well finished bunches of Alicante, and Mr. G. Mayer first prize large bunches of Prince of Wales and Lady Downe's Seedling. In size, colour and shade the bunches of Muscat of Alexandria shown by Lady Durning Lawrence were outstanding. The Duke of Newcastle won a first prize for a dish of Brown Turkey figs.

An exceedingly fine group of hardy fruits grown in the open air was exhibited by Major Wingfield Digby, for which he was awarded the Gordon-Lennox Challenge Cup. His apple varieties Bramley Seedling and Rev. W. Wilks and Pitmaston Duchess pears were in fine condition. A similar collection of hardy fruits won a first prize for Sir Charles Nall Cain. In this group the pear Marguerite Marillat was well ripened, and among the apples Bramley Seedling was of good colour.

Various market growers showed boxes of packed fruit. Dessert and culinary apples were packed in British standard boxes, while peach boxes were used for packing pears. In a few instances the grading could have been better, but on the whole the packing was well done. Lieut.-Colonel H. Lumley Webb exhibited prize-winning boxes of the dessert apple Benn's Red. The Hollesley Bay Labour Company had well packed boxes of Lane's Prince Albert, Allington Pippin and the pear Conference. Mr. C. L. Lewitt won a first prize for packing three peach boxes with the pear Doyenne du Comice. Four chip baskets packed with Black Alicante grapes won for Messrs. J. Almond and Sons a silver cup.

In the various divisions for distinct varieties of apples and pears there were a few varieties which always carried off the prizes. The pear Pitmaston Duchess, and Lane's Prince Albert, Warner's King, Newton Wonder, Bramley's Seedling, Cox's Orange Pippin and Charles Ross among the apples received many prizes and were the most popular varieties exhibited at the Show. Captain Drummond was successful in a number of classes. Lady Henry won first prizes for dessert and cooking apples. Annie Elizabeth was the best coloured variety in this particular collection. Mr. J. H. Loudon was another prize-winning exhibitor in several classes. Another very successful exhibitor in numerous classes was Mr. J. A. Stidston. In each case his fruit was large, even in shape and well coloured. Highly coloured specimens of Gascoyne's Scarlet were shown by Lady Knott. Mr. W. H. Myers won premier awards for a collection of apples; the Right Hon. Earl of Bessborough for Warner's King, Lord Derby, Ecklinville, Grenadier and others. Very excellent pears were shown by Lady Mary Morrison, the best varieties being Marguerite Marillat and Durondeau. Captain N. G. Chalmers Hunt had good specimens of the apple Rival: Mrs. Helsham Jones enormous Catillac pears; the Earl of Dunraven numerous well grown fruits, including highly coloured specimens of the apple Mère de Ménage. Allington Pippin was well shown among the dessert apples by Mr. F. J. Long; Major C. L. Gordon brought some fine apples from Scotland; the Earl of Coventry perfect specimens of Pitmaston Duchess pears; Sir William Lawrence good Margil apples; and Captain R. B. Brassey attractive fruits of the dessert apple Superb. Charles Ross and Bismarck were two of the best apple varieties shown by Mr. T. Sherrard; and among culinary apples Mr. F. C. Stoop's exhibit of King Edward won a premier award. Crawley Beauty and Golden Noble were two apples well shown by Sir Charles Nall Cain. There were numerous other prize-winning exhibitors, including Mrs. Austin, Mr. E. H. Sikes, Major Bibby, Mr. H. W. Henderson, Mr. C. R. Dunkey and Viscount Hambledon.

The Affiliated Societies Challenge Cup was won by the North Walsham District Horticultural Society.

There were many attractive trade exhibits. Messrs. Laxton Brothers staged a collection of apples and pears, including several of their fine new apple varieties. Lord Lambourne and the new highly coloured dessert apple Laxton's Superb, a late variety with a Cox's Orange flavour, were two of them. Messrs. T. Rivers had an excellent exhibit of apples in dishes and of pot-grown fruit. Peasgood's Nonsuch and Gascoyne's Scarlet shown by them were of remarkable size and colour and in perfect condition. Apples of many varieties were exhibited by Messrs. S. Spooner and Sons. Newton Wonder, Bismarck, Charles Ross and Allington Pippin were their best varieties.

Messrs. J. Cheal and Sons selected such varieties as King of Pippins, Chelmsford Wonder, Bismarck, Cornish Aromatic and Rival, all first-class varieties for the small garden.

A large and interesting exhibit was put up by Messrs. J. C. Allgrove. Pot fruit of all kinds, as well as dishes of apples, pears and plums, were on show. A pot-grown bush of Peasgood's Nonsuch was bearing a number of large and well coloured fruits, a bush of the plum President was carrying a good crop, and a dish of S. T. Wright was one of the best varieties which this firm had on show. The Barnham Nurseries had an extensive collection of pears and apples. There were numerous varieties exhibited suitable for both dessert and culinary purposes. Charles Ross, Baumann's Reinette, Adam's Pearmain and the good keeping apple Christmas Pearmain were a few of the varieties they selected. Some fine pears, such as Uvedale's St. Germain, Doyenne du Comice and Marie Louise d'Uccle were noticed among the fruit exhibit of Messrs. Daniel Brothers. Frontignan grapes (in several varieties), which are noted for their delicious musk flavour and which can be grown in a greenhouse without heat, were exhibited by Messrs. Bunyard. Pears and apples were also shown by them. Ellison's Orange, Ribston Pippin, Grenadier and Baumann's Red Winter Reinette were included in their collection.

Mère de Ménage, a dark crimson striped and flushed culinary apple, was among Mr. H. Hemsley's many varieties. Well grown specimens of Allington Pippin, Lane's Prince Albert and Williams' Bon Chrétien pear were also noted. Messrs. W. Hoopwood and Son chose, among others, the apples Annie Elizabeth, Wealthy, and Charles Ross for exhibiting with their fruit collection.

Other interesting features of the Show were a group of ornamental gourds shown by the Earl of Dunraven, and an enormous bunch of Black Alicante grapes weighing 37½lb. This bunch came from Belgium, and was exhibited by Messrs. Nash and Austin.

OUR SERVICE BUREAU

Though so many subjects are dealt with in each issue of THE GARDEN, *it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, there is always information available from a staff of expert contributors and consultants; and there is no charge for this. It is one of the additional means of service which* THE GARDEN *is glad to render to its readers.*

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope and the coupon, that will always be found in each issue, shall be sent with the enquiry.

We would point out, however, that we cannot undertake to supply readers with plans and designs of gardens, but will willingly assist in giving suggestions for planting.

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2.*

We have selected the following enquiries, with their answers, as being of more general interest, and therefore worthy of publication.

How to Prune Forsythia suspensa.

I should be so glad of advice as to the pruning of Forsythia suspensa; it has, somehow, been overlooked, and is now a mass of rather weedy

Digitized by Google

shoots, though most of these seem to have indications of flower buds. Where I shortened back some long shoots last year, I now have a fork with two new shoots.—G. C. H., Pinhoe.

The time for pruning Forsythia suspensa is after it flowers, in early spring. If you prune it just now, you will cut off the wood which bears the flowers next spring. You will need to leave it as it is at present, then, next spring, shorten back all the shoots, taking out all the dead wood.

How to Kill Daisies on Lawns.

What is the best chemical to use to mix with sand in order to kill daisies on lawns? I have plenty of sand and propose to mix the chemical here myself, as I have a large extent to dress it would be too costly to buy lawn sand.—R. G. A., Cork.

Hand-weeding is the most effectual way of getting rid of coarse weeds and daisies. But you may mix nitrate of soda with the sand. Dissolve one ounce of the soda in one gallon of water and water the liquid on spread-out sand, one bushel of the latter. This is a safe strength to use. The sand, whether one bushel or ten, should be turned over twice after being so watered, allowed to dry in an open, dry shed, then applied. The nitrate will cause a strong growth of the coarser grasses.

A New Rose Garden.

I am making new rose beds, four large diamond-shaped ones outside and four smaller inside, two corner ones to be reds and two pinks, four inside to be yellow and cream. The locality is between Cheltenham and Gloucester, and the position a wet clay. Eight roses wanted for the two reds, I think of General McArthur and Hugh Dickson; two pinks, Caroline Testout; four yellow or cream, Golden Emblem, Melanie Soupert, Mme. Ravary. These roses all do well with me, but there may be better ones. One and a half to two dozen in a bed would be the number of roses I should use.—C. S. G.

General McArthur is certainly one of the best red roses, and if you can grow Hugh Dickson well, it is certainly the best crimson. It sometimes varies in colour, and throws out two long shoots, but probably your neighbourhood suits it to perfection. Caroline Testout is, without doubt, one of the best pinks. For your other one I should be inclined to use Mrs. Henry Morse. It is rather subject to mildew, but this is only serious if it is allowed to grow rank. For yellows or creams you should include two which you mention, Golden Emblem and Melanie Soupert. For the third we should suggest Christine, whose only fault is that it is rather a smaller rose than the others, and for the fourth we should suggest the Rev. F. Page Roberts, which never loses its colour, even in the strongest sun.

Pruning of Cordon Fruit Trees.

I should be much obliged if you would give me particulars as to the pruning of first-year cordon fruit trees. I have just planted some of these, apples and plums, on the top of a bank which is protected by the house from north and east, and to some extent by low walls from all quarters but south-west. Will it be necessary, either now or later, to stake the trees? If so, I presume stakes should be placed at once to avoid disturbance of the roots later.—M. D., Dublin.

Cordon fruit trees should not be pruned during the first year after planting. They should be allowed to become established before any proper pruning is done. Any damaged or very weak shoots may be removed now, but severe pruning should not be attempted until next year, when the leader should be shortened back to within 18ins. of the ground and all side growths should be spur pruned. These young cordons should be carefully staked at once. They can be trained in an upright or in an oblique position, and a strong stake should be placed near the base of each tree. Strips of sacking should be bound round each tree in two positions, and these tied to the stake. This will prevent any rubbing. From time to time during the winter these ties should be undone and readjusted, as the ground nearly always sinks after planting, and the trees would otherwise become "hung" to the stakes. The stakes should be made of strong, well seasoned wood, and the portion in the ground should be tarred, as these stakes will be permanent.

How to deal with Unsatisfactory Hollyhocks.

I shall be much obliged if you can tell me why I cannot grow hollyhocks successfully in my garden. The plants at first appear healthy and strong, but as soon as the flowers appear the leaves begin to wither and turn black, so that as soon as they are in full bloom the plants are practically without leaves. I am not growing any this year on this account. —M. G., Guernsey.

It would appear that your hollyhocks are attacked each year by the dreaded disease hollyhock rust. This is a fungoid disease which in some districts is very serious. The spore clusters of the fungus occur as hard brown warts on the underside of the leaves and as elongated streaks on the stems. The chief causes of the spread of this disease are the growing of hollyhocks for too long a period in the same situation and poor soil. Hollyhocks are "gross feeders," and the soil in which they are growing soon becomes impoverished. The hollyhock site should be changed every few years and the soil well enriched. The plants should be treated as biennials. All hollyhocks infected with hollyhock rust should be burnt and the ground treated with lime, and you should avoid planting in the same position for several years.

Plants for a Trellis.

I have just completed laying out a garden of a new house. It consists of a lawn with a border all round 3ft. wide. The boundary fence is raised up to 6ft. with trellis. Will you please suggest a suitable plant to cover the trellis? I would like privet, but am afraid that would affect the flowers which may be grown in the border.—E. K., Wembley.

We should suggest that you might plant a rambler rose on the trellis which you mention if the soil is at all suitable for rose culture. If you do not like a rose, why not try an evergreen clematis, such as C. Armandii? If you wish shrubby subjects, we should advise you to grow one or two pyracanthas, such species as coccinea do rather well.

Shrubs for Shady Positions.

I have a semi-circular plot at the front of my house next the road, measuring, roughly, 36ft. by 15ft. At one side of this outside my garden there is a large chestnut tree, and I find that while the one half of this plot grows herbaceous plants well, nothing will grow in the other half, not even the grass border, the division being very striking. Can you tell me what to do with this? The soil here is very dry and sandy. I thought of planting the whole bed with flowering and ornamental shrubs. Would this be advisable and, if so, what kind should I get, and when?—H. C., Weybridge.

Your suggestion of growing a border of ornamental shrubs under a chestnut tree is, we think, a good one. You will, however, require to be limited in your choice, and only plant such kinds as do well in half-shade. You might, under the circumstances, plant such kinds as sarcococca (an elegant little plant for such a position), Euonymus radicans variegatus and Hypericum calycinum. This latter plant is an exceedingly pretty little evergreen, and soon forms a most effective bank under trees. Butcher's broom, Ruscus aculeatus, is also another good one. These can be obtained this autumn and placed in position within the next few weeks. These are all low-growing plants and would do well in such a position as you mention.

Cleansing Fruit Trees.

On removing old grease bands from apple trees, which had been untouched for two seasons, a number of maggots and other insects were found eating into the bark. Would you kindly advise what to do to destroy these without further injury to the trees? Do you advise lime washing the trunks in place of grease-banding, is it as efficacious and, if so, when should this be done?—B. M. S., Whitstable.

We should suggest that you spray the trunks of your fruit trees with one of the caustic washes during the winter months after the trees have been pruned. This is the most effective means of clearing the trunks of the trees from all lichens which harbour the eggs of insects. Care must be taken in applying the wash, and it is advisable to wear gloves, as the burning action is rather strong. Grease bands should still continue to be put on, however, if there is any chance of attack from the winter moth.

Mildew on Peaches.

Would you be good enough to advise suitable treatment for a peach tree that has suffered from mildew for two seasons? The crop was exceptionally heavy this year, but, unfortunately, very few ripened completely on the tree. It is on a south wall and was thoroughly syringed with sulphur mixture during the growing season, and I thought something might now be done that may prevent the misfortune next year.—E. O., Dorset.

A peach tree which has suffered from mildew should be well washed with Gishurst's Compound at pruning time. When the pruning is finished and before the tree is tied up again scrub the tree all over with a solution of this compound, which contains soft soap, paraffin and sulphur. Gishurst's Compound is obtainable from any horticultural sundriesman. Use a soft scrubbing brush for the main branches and a soft camel-hair brush for the thin laterals. Take care to brush upwards always so that the buds are not rubbed off. During the growing season we advise you to spray your peach tree with a mild solution of lime sulphur.

A Hedge Plant for an Exposed Position.

I have a bank 4ft. wide and 4ft. high, 60yds. long, made in June, of subsoil from virgin land (house building), with a foot of top spit on it. It faces south, and backs my garden. The site is very windswept. Can you suggest hedge for top of this bank to grow 6ft. about? Or taller? I intend to plant an herbaceous border in front of bank. The bank is dry. I thought of Berberis stenophylla or Olearia macrodonta. Mahonia too low and heavy probably too dry for this. Escallonia macrantha might do.—E. T., Porlock.

You might try Cupressus macrocarpa in the situation which you mention. It is a plant which will reach fully 8ft. in height, is quick growing and will stand a fair amount of exposure. It soon makes a bushy hedge if planted when about 3ft. high at intervals of about 2ft. apart, and makes quite a graceful hedge also. Certainly Escallonia macrantha would make quite a desirable hedge, but Cupressus macrocarpa would suit your purpose better.

ST. MARY AXE NDON, E.C. 3

Teles.: 1869 and 1870.

Teleg.: Phosphorus, Phone, London."

PUBLICATIONS RECEIVED.

"Rhododendrons for Everyone," by Capt. F. Kingdon Ward. Published by the *Gardeners' Chronicle*, Limited, price 3s. 6d. The rhododendron is no longer the plant of the specialist; it has become a commoner, suitable for all gardens, both big and little, and naturally with the increase in its popularity and its more extensive cultivation, there has arisen a demand for information in the growing of these shrubs. The present volume supplies the need to a certain extent. Much useful information is contained in the various chapters on garden rhododendrons, and rhododendrons in the wild, together with selected species and hybrids for general garden purposes. Although chapters on classification and distribution are mainly of interest to those who are enthusiasts, yet the beginner will find much useful information on the genus given in those chapters which will be valuable to him in the growing of the plants. It is necessary when dealing with such a large and widespread genus to evolve some concrete taxonomic basis on which to work and it is wise to give the beginner an idea of the system and its value to the grower. The beginner in rhododendrons will find the list of selected species and hybrids of great help in making a choice for his garden. The author has confined himself to species which are, on the whole, easily obtainable, which is a point of some importance.

The style is simple and lucid and essentially the author's own, so that the amateur will have no difficulty in understanding every page. It is well printed and remarkably free from errors in nomenclature. The eighteen illustrations are good in so far as they indicate, to some extent, the wide difference of size and form of the flowers of the various species, but a few reproductions of plants growing in gardens of this country would have been of more assistance to the lay reader, and give him an idea of the effects to be obtained by planting a few of the more common species in his garden. It is a helpful little book, inexpensive and one well suited to the needs of the amateur gardener.

"Violet Culture, for Pleasure and Profit," by F. E. Dillistone. Ernest Benn, Limited, price 2s. net. An instructive handbook, essentially practical in its outlook and information, which all amateurs should find of great assistance in the growing of violets, either on a commercial basis or in the private garden.

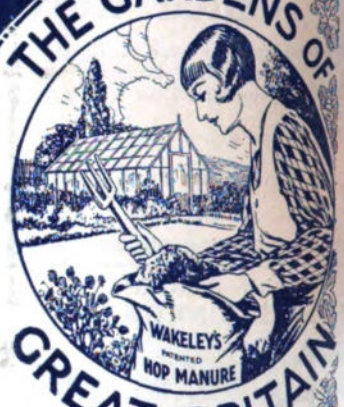
WAKELEY'S Celebrated Hop Manure

(PATENTED)

THE ORIGINAL AND ONLY RELIABLE SUBSTITUTE FOR STABLE MANURE

AS USED IN THE GARDENS OF GREAT BRITAIN



DIPLOMA AND MEDAL, ROYAL INTERNATIONAL HORTICULTURAL EXHIBITION, 1912

DO YOU REALISE IT?

A large bag of WAKELEY'S PATENTED HOP MANURE at a cost of only 7/- carriage paid to your door (if within 25 miles radius of London, or at a trifling extra if beyond), GOES AS FAR AS A CART-LOAD OF STABLE MANURE, without any of the defects of the latter; gives better results, is easy and clean to use.

Every ounce of Wakeley's Hop Manure is of value to the soil, supplying the necessary HUMUS in addition to the valuable plant food. Worthless rubbish is not added to make weight (as is the case of some artificial manures advertised).

Thousands do realise it, the proof of this is the constant flow of UNSOLICITED LETTERS received from time to time in praise of the wonderful results obtained at such a moderate cost (see Booklet for selection).

BEWARE OF IMITATIONS.—Genuine Only in our Marked Bags containing Guaranteed Analysis.

ILLUSTRATED CATALOGUE giving full particulars and testimonials sent on receipt of postcard.

20 Large	120/-

Carriage paid by Pickford's or to any station within 25 miles of London, including delivery if within free delivery radius of Railway Company; 6d. per bag extra for every 50 miles or part beyond. Maximum extra charge Great Britain, 2/6 per bag.

WAKELEY BROS. & CO., LTD.

75a, BANKSIDE, LONDON, S.E.1

Small Orchards

No matter how small or large the orchard, it pays to use Stictite Tree Banding Compound.

Winter Moth rises from the soil early in October or late September, and the females (being wingless), at once crawl up the tree trunks in order to deposit their eggs in the branches.

By banding the trees with Stictite in the autumn you can prevent the eggs being laid, and so avoid having to spray for the caterpillars in the spring.

1 lb. of Stictite will do 9 to 12 trees of about 8 in. diameter.

½-lb. 1/6 (post 6d.); 1-lb. 2/9 (post 6d.); 2-lb. 5/- (post 9d.); 4-lb. 10/- (post 9d.); 7-lb. 17/6 (post 1/-).

Greaseproof Paper, 5 ins. wide: 6 yds., 2d.; 12 yds., 3d.; 25 yds., 6d.; 50 yds., 9d.; 100 yds., 1/6; 200 yds., 2/6.

Write for Descriptive Folder.

Stictite is sold by Nurserymen, Seedsmen, Florists, Ironmongers, Chemists & Stores. If any difficulty, please write to Abol Limited, 9, Beltring, Paddock Wood, Kent.

Stictite

Recommended for Roses, Bulbs, all other Flowers and Fruit Trees.

NEW HARDY CRIMSON BROOM

AT Chelsea Show (1925) the King said, "That red Broom is certainly very striking." This was the new crimson Broom "Dorothy Walpole," which received the unanimous Award of Merit from the R.H.S. as well as other distinctions in London and on the Continent. Plants have been sent to U.S.A., Canada, Australia, New Zealand, France, Holland, etc.

In the Field, *a well known ex-Curator of Kew Gardens wrote: "The richest coloured Broom known is one named 'Dorothy Walpole.' It is as hardy as the common Broom . . . and is very free-flowering . . . the colour is rich velvety crimson . . . more attractive than any of the coloured Brooms yet seen." The colour far surpasses Cytisus Dallimorei, and the growth is as vigorous as C. Andreanus; it requires no special treatment nor any kind of protection whatever—just a hardy shrub for ordinary garden soil in any part of the British Isles, however far north.*

A Vice-Chairman, Floral Committee, R.H.S., wrote: "Everyone who has seen my plant has been astonished at its warm glowing red"; and from a lady in Devon: "I am so delighted with the Broom 'Dorothy Walpole.' It has done splendidly and is like a sparkling gem in the garden—one mass of flower."

NEW SEASON'S PRICES.

Strong pot-grown plants now ready for planting out, to flower in May, 7/6 each. Carriage paid rates to any station in Great Britain or Ireland: One plant, carriage paid, 10/-; two plants, carriage paid, 18/6; three plants, carriage paid, 26/-; six plants, carriage paid, 49/6; twelve plants, carriage paid, 99/-.

CAPE PLUMS.

This group of Plums is descended from Prunus salicifolia, a Chinese species, but the exports from South Africa during the winter have led to the name given above. Not hardy enough to fruit outside in this country, they are most interesting orchard house plants in pots or trained on walls, and we offer three varieties: Abundance (Burbank), golden yellow and red; Botan, garnet red—the best flavoured; and Shiro, golden yellow, of enormous size. All are rather early ripening. Bushes and Fans are 7/6 each.

George Bunyard & Co., Ltd., The Royal Nurseries, Established 1796. Maidstone.

SPECIAL OFFER of FIRST-GRADE TREES and SHRUBS

LARGE ENOUGH FOR IMMEDIATE EFFECT

All wind resisters excepting the Acacias

SENT INEXPENSIVELY PER GOODS TRAIN AT LOWEST TREE-RATE

Packed Free for Cash with Order.

	Each
Acer Negundo, an elegant maple with pale green compound leaves, 8-12 ft.	3/6 and 6/6
Acer californicum, "The Californian Maple," very distinct and beautiful, 6-7ft.	3/6 ,, 4/6
Acer latum rubrum, the young growths are beautifully tinted red; butter yellow in the autumn, 8-10ft.	5/6 ,, 7/6
Acer platanoides (Norway Maple), beautiful large green leaves, turning golden yellow in the autumn, 8-12ft.	3/6 ,, 5/6
Acer plat. Schwedleri, the purple leaf variety; beautiful coppery foliage, April to November, 8-12ft.	6/6 to 10/6
Acer pseudo-platanus, "The Sycamore," a grand "wind screen," 8-16ft.	4/6 and 7/6
Acer pseudo-plat. purpurascens, "Purple Leaf Sycamore," 8-12ft.	5/6 ,, 7/6
Alnus cordata, very rapid growing, excellent for marshy areas and poor chalky soils, 12-15ft.	5/6 ,, 7/6
Alnus incana, "The Grey Alder," do. do. 14-16ft.	5/6 ,, 7/6
Betula japonica, rare Japanese species, one of the most beautiful of all silver barked trees, 8-10ft.	5/6 ,, 7/6
Crataegus prunifolia, "American Thorn," superb for flower, berry and autumn colour, 6-9ft.	4/6 ,, 5/6
Fraxinus americana, the American "White Ash," a distinct and noble tree of fast growth, 4-5ft.	2/6 ,, 3/6
Fraxinus excelsior, "The Common Ash," excellent for wind-swept and coastal situations, 9-12ft.	3/6 to 6/6
Juglans regia, "Walnut," 9-12ft.	7/6 ,, 10/6
Ostrya carpinifolia, the striking "Hop Hornbeam," 8-10ft.	5/6 and 7/6
Pterocarya stenoptra, new fast growing Chinese tree, with wonderful foliage, 9ft.	5/6
Poplars in great variety, 9-16ft.	3/6 to 10/6

Write for our special offer per dozen, 100 and 1,000.

	Each
Robinia, in a variety of colours. More commonly known as the "Acacia," one of the most elegant trees extant, 9-12ft.	5/6 and 7/6
Sophora japonica, the finest of the late autumn flowering trees, 8-10ft.	5/6 ,, 7/6
Ulmus, "Elms," in great variety, including americana, latifolia and nitens hybrids, 9-15ft.	4/6 to 7/6

A collection of one each of the above 20 trees, good specimens, for £5

SPECIMEN FIRS, PINES, ETC.

	Each
Pinus Banksiana, the American "Jack Pine," grows in poor sandy soils, 3-5ft.	3/6 and 5/6
Pinus densiflora, the Japanese "Red Pine," 3½ft.	4/6
Pinus excelsa, "The Himalayan Blue Pine," 3ft.	5/6
Pinus Strobus, "The Weymouth Pine," 3ft.	3/6
Picea alba, "The Giant White Spruce," 3-4ft.	3/6 and 5/6
Picea asperata, heavy specimens of this rare Chinese species, 4-5ft.	10/6 to 21/-
Picea obovata, "The Siberian Spruce," 4-5ft.	5/6 and 7/6
Picea pungens glauca, the "Blue Colorado Spruce," 1½ft.	5/6
Abies nephalensis, rare, 1½-2ft.	3/6 ,, 5/6
Abies numidica, rare, 3ft.	7/6
Abies concolor violacea, beautiful deepest blue foliage, 2ft.	7/6
Tsuga canadensis, the elegant "Canadian Hemlock Spruce," 3-4ft.	5/6

One each of the above 12 Conifers for **60/-**

12 Flowering Shrubs (Deciduous and Evergreen), in 12 varieties, 2-5ft.	doz., 12/-;	100	125/-
12 ,, ,, ,, ,, Choice newer varieties, 3-5ft.	doz., 36/-;	100	250/-

All to name, distinctly labelled, in beautiful variety, our selection of sorts.

THE GARDEN

VOL. XC.—No. 2865. OCTOBER 30, 1926. PRICE TWOPENCE.

NOTES OF THE WEEK.

The Greater R.H.S.

THERE is nothing that shows the increased popularity of gardening better than the growth of the Royal Horticultural Society. From a small beginning 124 years ago it has now increased to the gigantic total of over 23,000, with every sign that year by year the membership will increase. That the prosperity of the premier horticultural society of the world is no whit behind its membership was shown on Tuesday, October 18th, when the President, Lord Lambourne, laid the foundation stone of the new hall behind the present building in Westminster. Details of the new building have already been given in the Press, so it is unnecessary to say more than that the floor space is 20,000 sq. ft., exactly double that of the present hall. This will relieve the congestion that has often occurred in the more popular fortnightly shows during autumn and spring. No one will deny that the Royal Horticultural Society is doing an enormous amount for our gardens, and that those who guide its destinies are worthy of the greatest praise for the work that they are doing for British horticulture.

Imperial Fruit Show, Holland Park Hall, London.

OCTOBER 29TH TO NOVEMBER 6TH.

AMATEUR gardeners and others interested in horticulture should not fail to pay a visit to the Imperial Fruit Show at Holland Park Hall. The fruit entered for competition at this exhibition, grown by the greatest experts in this country and in the Dominions and Colonies, represents the high-water mark in cultivation, and will prove of great interest to all growers of fruit, whether amateur or commercial. Well known firms of nurserymen, insecticide manufacturers and horticultural sundriesmen have taken stands at the Show and will be ready to give advice to all enquirers. The Ministry of Agriculture are staging a special exhibit. The Royal Horticultural Society have arranged for a special display of fruit, flowers and evergreens from their gardens at Wisley. The most prominent feature at the Show will be the combined exhibit of the great fruit-growing Dominions—Canada, Australia and South Africa—covering an area of over 3,000 sq. ft., under the auspices of the Empire Marketing Board. An interesting competition has been arranged for baked apple dumplings (using Empire fruit only), the entries in which will be staged daily at the show. Superb exhibits of fruit are being arranged by some of the greatest distributors in the United Kingdom. The Show is open from 10 a.m. to 9.30 p.m. daily.

Delayed Planting.

AT this season of the year, when early frosts often follow close on the heels of the drought of late summer, gardeners are inclined to be alarmed at their inability to plant, and also at the non-arrival of plants which they may have ordered. The truth of the matter is that weather, and not the date, is the deciding factor in planting. Owing to the long drought in some parts of the country, followed by a sudden frost, many nurserymen have been unable to lift plants for despatch. It really matters little when planting is done during the next few months, provided that the ground is not frosted or the soil too wet and water-logged. Even bulbs like daffodils, and particularly tulips, are all the better for being planted in open weather after the first touch of frost. The planting of all fruit trees, deciduous trees and shrubs and almost all herbaceous plants can be suitably accomplished in any open weather. If plants happen to arrive when the ground is too damp or frosted, they can be kept quite well for several days on the floor of a shed with their roots covered with straw or earth, so long as the roots are not allowed to get too dry. The vagaries of our climate are such that you cannot say that you will plant on such and such a date.

HAVE YOU

- ¶ *Pruned and trained your rambler roses?*
- ¶ *Lifted your dahlias which have shown signs of injury by frost?*
- ¶ *Replanted in a freshly prepared bed your lilies of the valley that have become overcrowded?*
- ¶ *Patched, weeded and top-dressed your lawn?*
- ¶ *Lifted (after flowering) a certain number of your border chrysanthemums? These, if cut back, boxed up and placed in a cold frame, will furnish cuttings in the spring.*
- ¶ *Prepared your ground ready for planting as soon as the weather permits, fruit trees, shrubs and herbaceous perennials?*
- ¶ *Completed the lifting and storing of your root crops?*
- ¶ *Repaired the woodwork of your arches and pergolas?*

Securing Chrysanthemum "Sports."

MANY fine forms of chrysanthemums have been secured from what are known as "sports." These arise in a curious way that is not very clearly understood. Now and again, for no very apparent reason, one stem of a chrysanthemum plant will develop flowers that are more or less distinct from those on the specimen as a whole. Of course, the variation may be very slight indeed, but, on occasion, something new and really striking may arise. Any grower of chrysanthemums may find a "sport" of merit on one or other of his plants, and it is useful to know that the variety can be easily propagated.

It is supposed that a "sport" has appeared on a chrysanthemum plant which is growing in a pot. After the novel flower has been examined, and perhaps shown to a few of one's gardening friends, it is just as well to pinch it off altogether. Now fill a box or a pan with light sandy soil. Raise this on bricks or a box of suitable height until it is just about on a level with the rim of the pot in which the chrysanthemum is growing. Now carefully pull over the stem which has borne the "sport" until you can get it down to a nearly horizontal position on the soil in the pan or box. To do this it may be needful to ease the roots at the base of the stem a little, as on no account must it be broken away from the parent plant. Then make little nicks with a knife on the part of the stem which will be close to the soil, cutting just below where the buds are to be seen at the base of the leaves. These cuts must be very slight indeed and should not be carried more than a third of the way through the stem. Next, peg the stem down on to the soil, using a number of small forked twigs for the purpose. Sprinkle a little soil very lightly round the positions where the leaf buds are. The new plants arise from these buds and they root freely in a temperature which does not fall below 45° Fahr. Even where no artificial heat is available, the establishment of the little plants is only a matter of time. Rather a close atmosphere favours speedy growth, and protection with a sheet of glass is helpful.

PLANTS AT THEIR BEST IN AUTUMN

Gardeners are always glad to receive information about plants that have been particularly noted in other gardens. Week by week plants that are really worth growing are described in this page.

Begonia Rex: A Greenhouse Plant of Tropical Luxuriance.

AMONG the indoor plants which have gradually slipped from their one-time popularity must be reckoned the handsome, richly coloured foliage begonias, but it is strange, indeed, that so beautiful, yet so good-natured and easily grown a plant as Begonia Rex should lose its hold upon the affections of anyone interested in a conservatory or a small greenhouse.

Few plants are more capable of sustaining friendly companionship with a miscellaneous assortment of plants, especially with such as prefer semi-shade rather than glaring sun, and a tolerably moist, rather than a hot, dry atmosphere.

With temperate orchids B. Rex is happily at home, while it thrives beautifully under the conditions that best suit fuchsias, and will give colour and variation of charm to a fernery. The question is constantly being asked by amateurs what they may safely and successfully grow under a grape vine, and it would be difficult to find a more suitable subject for the purpose than B. Rex, which, by the way, may be had in many variations of colour markings and size of leaf.

The plant shown in the illustration is one of a small batch which the writer rescued from a house which, through unavoidable circumstances, had been left unattended from February till May. Fortunately, it stood under a broken pane of glass in the roof, otherwise death for want of water would have been inevitable. When taken in hand the plant was a mere stump, with but one half-dead leaf and some very weak roots. It was shaken out and repotted in a compost of loam, a very little peat, some old mortar and sharp sand. The pot is 4½ins. in diameter and into the compost was mixed just about a teaspoonful of dried, pulverised sheep's manure. Watering was moderate at first, but the hard stump was moistened twice daily with a syringe. When leaves developed, water was given in increasing quantities, and syringing has been maintained throughout. The wonderful recuperative power of the plant is well demonstrated by the photograph taken on August 17th, which also shows the handsome character of the foliage.

The large leaf measures 15½ins. in length and just over 8ins. across its broadest part. Should not B. Rex be restored to popularity and widespread cultivation?

Ivy-Leaved Pelargonium Souvenir de Charles Turner.

RIGHT until frost actually ruined the plants, this large and particularly bright cerise-coloured variety bloomed on as most ivy-leaved pelargoniums do in July and August. That is its greatest point of merit, although in shape, substance, size and colour it leaves Mme. Crousse, Ryecroft Surprise, Galilea and other popular varieties behind.

Objection has sometimes been raised against Souvenir de Charles Turner on the ground that it is a lazy bloomer. It is late, as already remarked, and valuable on that account, but when it fails to flower freely in autumn it is due to cultural errors.

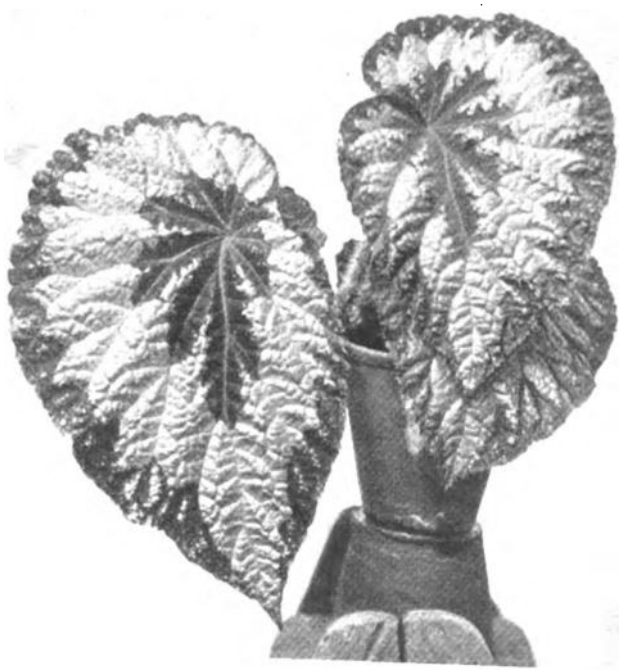
The plant must be given a restricted root-run; it is better adapted for pot culture than for bedding, and the pots should be small, well crocked and the soil should consist of strong loam with plenty of sharp grit and no leaf-mould. Under such treatment, and given plenty of light and air, there will be no need to complain of lack of bloom.

Cut-back plants of this variety may spend two seasons in pots of no more than 5ins. diameter, but the second season they require some feeding with liquid manure.

A Fine Purple-Leaved Filbert.

JUST as the leaves are clinging as in desperation to their branches, the colour of Corylus Avellana purpurea is particularly rich and of quite uncommon beauty. It is a shrub for prominent positions, in the garden as well as in the wilder shrubbery, for it can be kept to almost any desired dimensions, and still retain its pleasing habit of growth, and there is a lustre upon its purple foliage which nothing else can fully reproduce. Layering is a ready means of producing young stock, and it is also a means of extending the breadth of a single plant where spacious grounds demand massed effects. The ripened growths of the year which spring from the base of a plant cut hard back in February or March should be bent to the ground and held in position by strong wooden pegs. Gritty soil encourages rooting. Where the object is to increase the size of a clump a ring of layers may be pegged down all round the main stool and left to grow at will.

When young plants are required for removal they should be given a twelve-months' round, when they may be severed and will lift with plenty of fibrous roots. This purple-leaved variety, like all the filberts, will thrive on soil which is too harsh and stony for many shrubs of no greater beauty.



THE MAGNIFICENT FOLIAGE OF BEGONIA REX.

Euonymus Radicans Silver Queen.

IT is now, when colour is becoming scarce in the garden, that the cheery effects of which this accommodating little silver-leaved shrub is capable are brought forcibly home to us, for in each of four distinctly different styles it is growing with abundantly satisfactory results. I have it in the form of corner bushes, kept neat but not too precise in outline by the simple process of pinching out the points of growths whenever and wherever they threaten to run away.

It is noteworthy that visitors who are not expert in gardening matters invariably enquire the name of these little bushes, and ask if they could be grown in some position or other for which something effective but not large is required. The second purpose the plant amply fulfils is as an edging to a border occupied by flowering shrubs and a few perennials of permanent character such as peonies, incarvilleas, kniphofias and eremuri.

Planted when small, from a cutting bed, the roots were first put in at 18ins. apart, to spin out a limited number of plants over a border of considerable length. During the first season's growth every stem was pegged into line as soon as its length permitted, cheap, stout hairpins being used for the purpose. The joints all rooted where they touched the soil, and a continuous line of neat variegated foliage quickly resulted. Now it is merely a case of occasional trimming to maintain a most effective edging which sustains interest in the border when the perennials are underground and the shrubs bare.

The third mission of the same little worker is to tumble over the edge of a low retaining wall holding up the end of a made-up-to-level tennis court. Here it effectually hides the fact that the wall was constructed of ugly clinkers because they were the only cheap material ready to hand when the making of the tennis court was a sufficiently heavy expense. The final use of Euonymus radicans Silver Queen to which I will refer is as a pot plant to furnish a window sill when frost has finished the autumn show of ivy-leaved pelargoniums. Four cuttings in a 48-sized pot kept pinched until they throw lateral branches to envelop the pots completely right to their base provide plants for the purpose named which would be hard to beat. Any piece of growth with three joints and a growing point will make a cutting.

Chrysanthemum Phœnix.

THIS red-bronze chrysanthemum has been long enough now in cultivation to take its place among the tried and proved varieties, and for garden use it has few serious rivals. Whether massed in a bed, dotted about in clumps in the mixed border, or grown in a thin single line alongside a straight path through the kitchen garden, its neat habit, even growth, rigidity of stem and warm cheery colour combine to make it a real autumn treasure. It needs neither staking nor disbudding, neither is it one of the fair-weather varieties which collapse when there are either showers or successive fogs. As a flower for cutting it has exceptional merits, but at the moment we will be content to recognise its garden worth.

A. J. MACSELF.

Digitized by Google

THE ROSE GARDEN

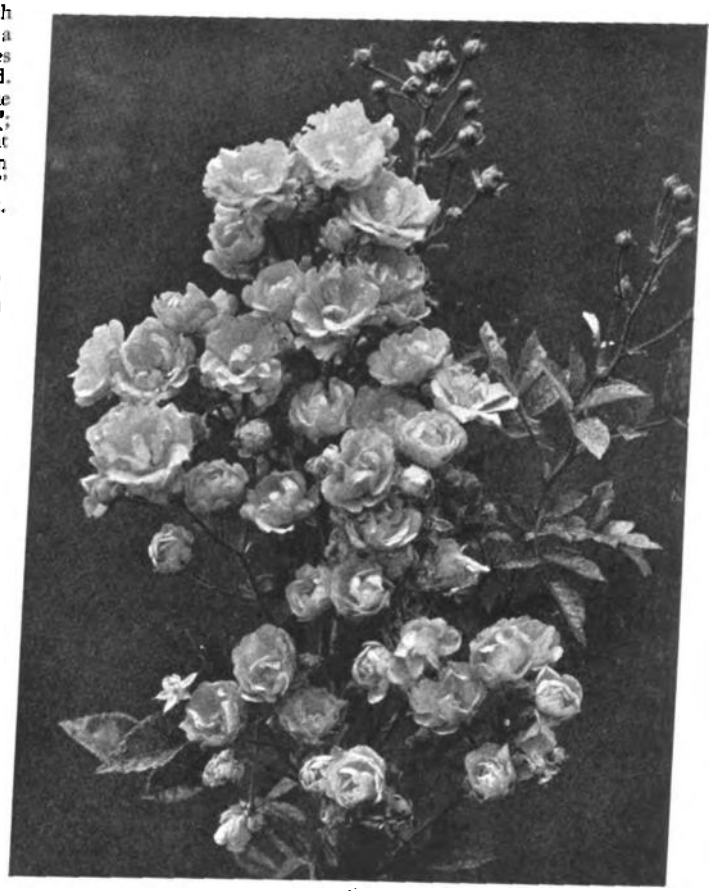
Dwarf Polyantha Roses.

I HAVE always looked upon dwarf polyantha roses as flowering shrubs, par excellence, for the small garden and yet I must admit they are only becoming popular very slowly. Their merits are many, but not the least is the fact that they flower profusely in fair weather and foul; in fact, it may safely be said that good bushes are smothered with blossom and this blossom persists with great freshness over a long period of time. They are capable, too, of many uses; I like them as an edging to a rose border; they make beautiful beds in themselves, however, and even as dot plants in a border they are excellent. Not often are they seen in a rock garden and yet a fine rockery which I visited the other day owed some of its charm to little rose dells where the polyanthas bloomed. There are many varieties of these polyantha roses, just too many to let a man be happy—without them all; new varieties find their way into commerce almost yearly and yet the good old kinds cannot be done without. No good collection, for example, would fail to include those fine old varieties Maman Levavasseur, Mme. N. Levavasseur, Perle d'Or, Perle des Rouges, Mrs. W. Cutbush, Orleans Rose, White Pet, Red Ridinghood, Snowstorm, Jessie and, perhaps, a few more. Of the newer kinds one must also get Coral Cluster, Edith Cavell, Carrie Koster, Comtesse du Cayla, Orange King, Dorothy Haworth, Reine Elizabeth, Resplendence, Chatillon and Baby Faureux. One does not see these fine little roses as standards very often nowadays; this is to be regretted for, fine as they are in the natural bush form, they are greatly enhanced in the standard and half-standard style. Beginners and amateurs who have not yet taken to these dwarf roses may, with confidence, select a few from the varieties I have enumerated. Any good catalogue will give the colours; they may be bought singly or, better, in numbers to "mass" or give greater effect.
—LANARKSHIRE.

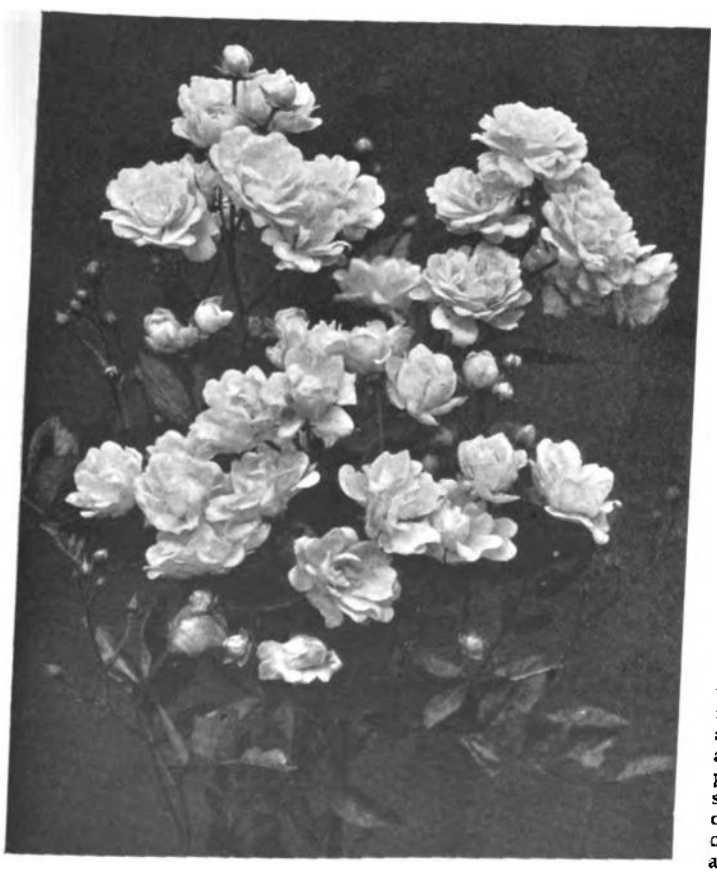
Planting Roses.

THE rose, leafless and possessing a few straggling roots, is not a very ornamental plant and it often gets poor treatment just at a time when it needs very careful handling. Of course, all growers cannot plant their roses just when they wish to, as circumstances will not always permit this to be done; but the ideal time extends from the last week in October to mid-December. Roses may be planted when the soil is dry enough, any time from November to March, but spring-planted roses need more attention than autumn-planted ones and even then, do not, as a rule, succeed as well. We presume that the soil is duly prepared at the right time and the plants ordered from the nurseryman. If the distance between nursery and garden is a short one, the roots will not dry considerably if the plants are not delayed in transit. But if they are or the journey is a long one, unpack at once and instantly immerse the roots and half the branches in a cistern or tub of water, leaving them there several hours. Make up a mixture of clay and water or stiff soil and water to the consistency of paint; dip the roots in this solution before planting and plant while the stuff is wet on the roots. I am sure that this is a desirable course, especially where light soils obtain. Standards and half standards should be staked as they are planted.

Although it is advisable to dip the roots in wet soil so that it will adhere to them, it is a good plan to have some fairly dry soil at hand so that a spadeful of it can be spread over the roots before any border soil is put on; this is very essential when the soil in the garden is rather wet. Do not plant in frozen soil nor when the air is frosty. Plant standards 30ins. to 36ins. apart, and dwarfs 24ins to 30ins. apart. Plant just the same depth as the roses were when growing in the nursery; look at the soil mark on the stem to ascertain this. Place a few shovelfuls of fine soil between the roots, then put on the final layer of soil and a surface mulch of short litter. Do not tread down the soil, allow it to settle gradually.—G. G.



ORLEANS ROSE PRODUCES CLUSTERS OF NEAT FLOWERS FOR MANY WEEKS.



CORAL CLUSTER IS ONE OF THE BEST OF THE DWARF POLYANTHA ROSES.

Mulching Rose Borders.

CONFLICTING advice is frequently received from gardeners, when guidance as to the proper procedure to follow out during winter is asked for. One man will tell you that frost ought to be allowed to ameliorate the soil and to kill soil pests; the other will state that frost may kill the bushes to the ground if they are not protected. After years of experience I have come to the conclusion that mulching of the finer bush roses is distinctly advisable; the stems are then protected and seldom suffer below the mulch level, even in the most severe weather. I find, however, that mulching with strong manure has an adverse effect on the soil, rapidly souring it and finally doing harm where it might be expected to do good; obviously, then, strong manure is inadvisable. Light, strawy or littery stuff, composed largely of straw or of peat litter with little manurial matter in it, is the best mulch to use, affording protection while

Digitized by Google

at the same time not acting deleteriously against the soil conditions. Ferns, bracken, rotten straw, spent hot-bed material also serve, the manurial elements being practically non-existent and the protective property strong in evidence. I have also tried ashes, old potting soil and earthing up; the first-mentioned is rather difficult to manage, the second material rapidly gets scattered by rains, wind and birds; while the earthing up, only possible in porous light soils, causes flooding and souring in a heavy retentive loam. Experience is a wise guide, and I have no hesitation in urging most readers to mulch their roses soon and to use some light protective covering which can be banked up round the bushes and in among the branches.—CLYDESDALE.

Roses in Gravelly Soil.

ROSES grown in a porous, gravelly medium are not always of first-class standard, the main reason being that such soil conditions are far from ideal in growing these fine flowers. The correct time to remove the disadvantage, or at least to render it a less potent cause of dissatisfaction, is when planting the bushes; such as have already been grown for some years, may quite well be lifted at this time and treated like new shrubs.

The best substance to use in order to have good roses is turf, and fairly fresh turf, too; in fact, it may be newly cut, but storage for a month or two is not in any way against it. Let holes be dug for the bushes, the subsoil may be left alone, as a rule. In the bottom of the hole put a good thick layer of turf, fill in with smaller pieces and plant the rose bushes in the centre of each, treading the turfy lumps firmly, very firmly, about the roots. That which comes into actual contact with the roots may be chopped up to "hen's egg size," but the rest need not be broken up, in any great degree. Spread a layer of fine soil over the surface.

Next best we hold to be that fine black mould obtained from decaying garden rubbish. In most gardens all soft rubbish is placed in a large heap and allowed to decay into a fine earthy matter; this, mixed with some of the soil underneath the heap, becomes a fine moisture-retaining compost, fairly rich and excellent for planting roses or for similar purposes. Dig a hole as above; if possible put turf in the bottom of it and then fill up with the black mould; plant firmly.

It may seem strange to some that we place manure third in the list. Manure has several disadvantages, not the least of which is that, in light, gravelly loam, it disappears much too quickly and the benefits originally derived from its presence cease. Cow or pig manure is undoubtedly best, and fairly fresh, too; do not let it come into actual contact with the roots, but let it be well mixed with the subsoil below the roses and again let some be added to the soil immediately over the roots. The layer of manure and soil immediately over the roots is all important for, under it, the soil remains moist and sappy for a very long time, even in droughts; it can, moreover, be renewed annually.

During summer, roses in gravelly soil not treated recently, must have a mulch; the mulch need never be unsightly, and it does not require to be a feeding mulch, otherwise the effect of the flowers is spoiled. Spent litter, peat, mushroom bed manure, hot-bed manure, lawn mowings, all serve the purpose well; not one of these is actual manure in the ordinary sense, but pleasant forms of mould, attractive rather than otherwise.—H. AITKEN.

Twelve of the Newer Roses.

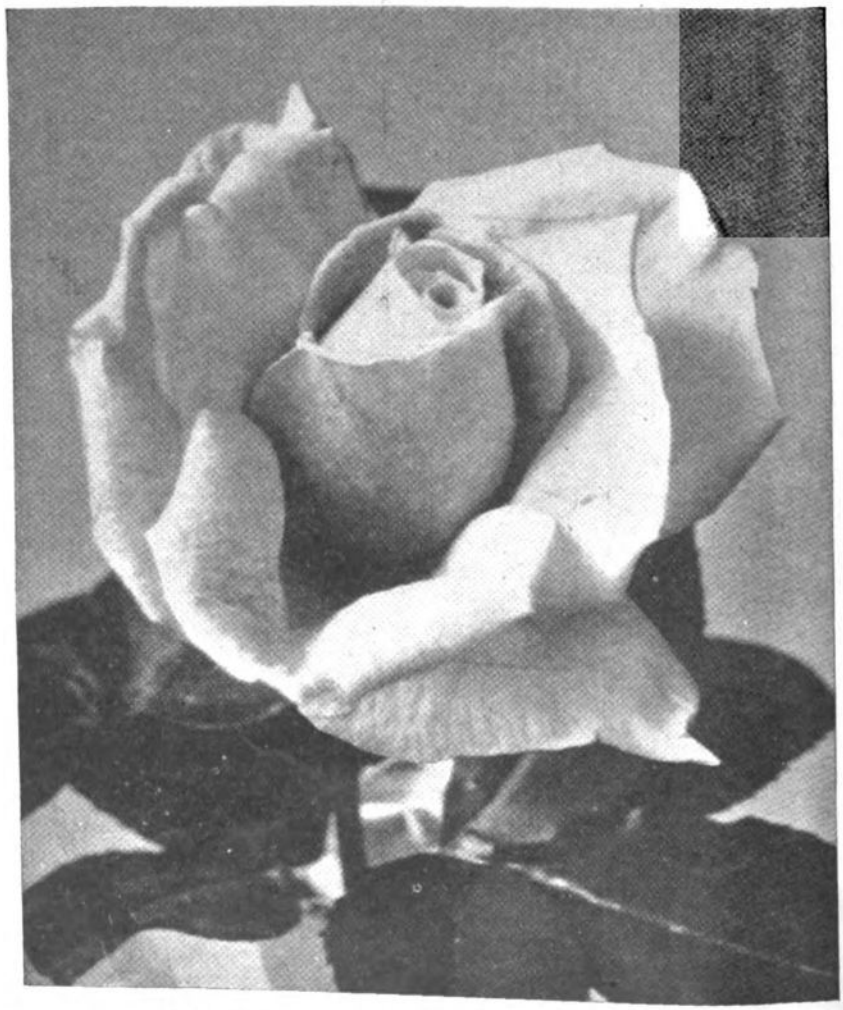
EACH year there are many introductions into the rose world, some of which stand the test of time, while others soon fade away to be heard of or seen no more. A number of the roses raised within the last four years are already becoming widely known and have surely come to stay, as they are proving of good constitution, resistant to mildew and black spot and most effective for garden decoration. Among these is Marcia Stanhope, a pure white bedding rose, which is free in habit. It is one of the most sweetly scented of all white roses and gives the best results when it is pruned lightly. Betty Uprichard is another rose whose popularity is increasing rapidly. Its blooms are medium in size and perfectly formed, with the inner face of the petal soft salmon pink, while the reverse surface is bright carmine pink. Betty Uprichard is a highly decorative rose, which, according to many reports, succeeds extremely well as a bedding rose in various districts all over the country.

Lady Inchiquin, a variety of brilliant orange cerise, has been introduced for several years and yet is not as well known as it deserves. Its chief attraction lies in its distinct and unique colour, but at the same time it has other points, such as sturdiness of growth and freedom of flowering, to recommend it. One of the best of the new roses for keeping its colour is Bedford Crimson, the 1924 winner of the Clay Cup, a challenge cup which is presented annually for the best rose with the true old rose scent raised during the current year. Bedford Crimson keeps its deep velvety crimson colour in all weathers, and a bed filled entirely with this variety when smothered with its fragrant blooms carried on long, stiff stems, is a beautiful sight. Two other good new crimson varieties are Scarlet Glory and Arthur Cook, the latter being the winner of the Clay Cup in 1925. Scarlet Glory is of a particularly lovely shade of vivid vermilion scarlet. It produces its flowers freely over a long period, and is fragrant as well as vigorous. The blooms of Arthur Cook are large and full, the foliage is mildew proof and bright green, and habit of the plant upright and free. This variety is especially suitable for massing.

A most attractive and outstanding introduction is Dainty Bess, a single-flowered hybrid tea. It bears a large truss of deep shell pink blooms, whose petals are prettily crinkled and waved. Each bloom has a conspicuous cluster of golden stamens. The reverse of the petals is of a deeper shade, and the flowers are even larger and more freely produced than in the case of K. of K., one of its parents. Dainty Bess is valuable for beds and borders, as well as for house decoration. Dame Edith Helen is one of the best of this year's roses and is a variety which shows great promise for garden decoration. Its constitution is claimed to be good, its foliage mildew proof, while the lasting quality of its blooms are certainly superior to the majority of recent introductions. It will remain fresh in water as long as a fortnight or more. The colour of this variety is bright, clear pink, the flowers large and substantial. Its fragrance cannot be doubted, for it was awarded the Clay Cup this year.

Among the new yellow roses are Mrs. Beatty, a pale yellow variety of perfect shape, whose growth is free and vigorous, and Roselandia, a deep yellow sport from Golden Ophelia. Roselandia has long pointed blooms, and dark, glossy green foliage. It is a variety which is most suited for growing under glass.

Two other roses which should be mentioned are Kirsten Poulsen, an orange scarlet dwarf polyantha, and Allan Chandler, a vivid scarlet pillar rose. M. P.



MRS. BEATTY, A BEAUTIFUL PALE YELLOW ROSE.

Plants for Hot Dry Soils.

HERE are a few plants which flourish in dry soils and enjoy a sun-baked position.

ACHILLEA PTARMICA THE PEARL (YARROW).—*A good border plant 2½ft. high which produces masses of small double white flowers in July and August.*

ALSTROEMERIA AURANTIACA.—*This beautiful Peruvian lily is very useful for establishing in a dry border. It bears orange flowers on 2ft. stems.*

ALYSSUM SAXATILE CITRINUM (MADWORT).—*An easily grown sulphur yellow dwarf plant suitable for carpeting, edging or clumps in the rock garden.*

ARMERIA BEE'S RUBY.—*A giant thrift with bright red flowers. It grows to a height of 1½ft. and blooms during June and July.*

CISTUS FLORENTINUS.—*A rock rose of dwarf and spreading habit. The flowers are large and snowy white.*

ERYNGIUM GIGANTEUM.—*The ivory thistle which produces flower bracts and stems of glistening ivory shade.*

HELIANTHEMUM COCCINEUM.—*A brilliant crimson-flowered sun rose suitable for a corner in the rock garden. The sun roses are all dwarf evergreen shrubs, and there are many varieties which are excellent for hot, dry soils.*

POLYGONUM VACCINIFOLIUM.—*A trailing knotweed of shrubby habit. It bears bright rose-coloured flowers in August and September. It grows about ½ft. high and is suitable for the rock garden.*

VERBASCUM PHŒNICEUM.—*A handsome mullein of 2½ft. high. It bears purple flowers on slender stems from June to August. This mullein is light and graceful in habit and can easily be raised from seed.*

Chrysanthemum Cuttings.

THERE is no doubt that the finest specimen plants of chrysanthemum are secured by starting the cuttings in November. Select only the very healthiest cuttings and plant singly in small pots of light soil. Then plunge these in fibre or similar material in an old hotbed where there is just sufficient heat to help forward the production of roots without encouraging too much top growth. In this position the young plants may be kept through the winter just slightly on the move, receiving plenty of air in mild weather and protected with mats during times of severe frost. The object in view should be to secure a sturdy, vigorous growth with the production of plenty of roots. Of course, autumn propagation of chrysanthemums means that one will have the plants on hand for a full year, but growers who try this method will usually consider that the results more than justify the amount of trouble involved.

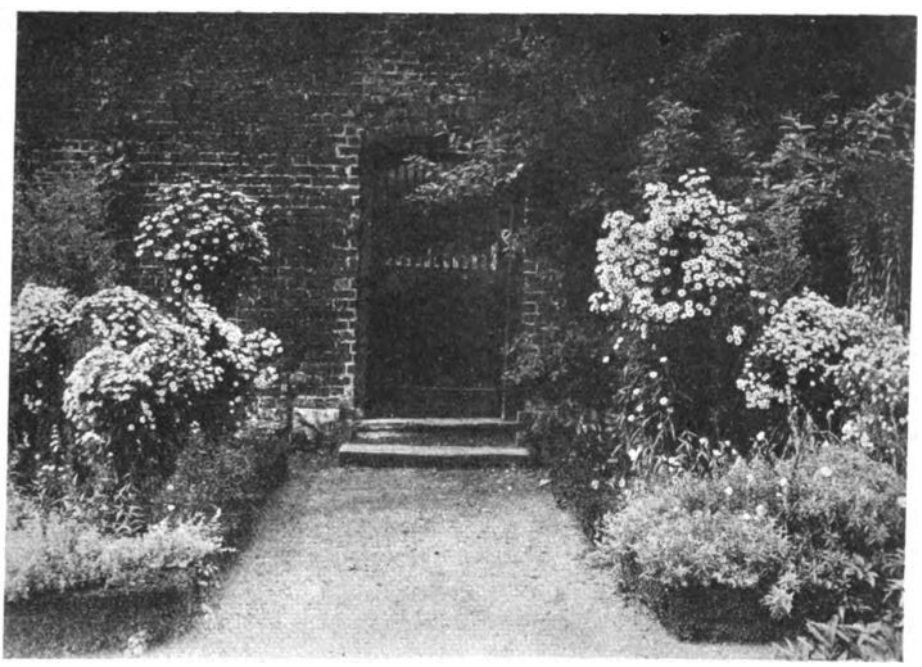
Prepare for Rough Weather.

IT is important at this time of the year that fruit trees, especially those that have been newly planted, are well secured. It is a very bad thing indeed when the wind not only shakes the trees, but the roots as well. Half-standards should be fixed to a post driven into the ground, the best tying material being a band of hay. If hay cannot be obtained, use tarred string, but protect the trunk against chafing with a narrow band of sacking. Bush fruit is secured to a shorter stake in the same way. For cordons erect at intervals stout posts and, from post to post, have lengths of three-stranded wire. Tie the stems of the trees to the wire with raffia. Trees on walls should be secured with nails having leaden flanges which can be turned over. If these are not used, ordinary nails and loops of cloth serve the purpose very well.

Michaelmas Daisies.

IN gardens of limited space, Michaelmas daisies are more likely to become a nuisance than a pleasure, because of their rambling and trespassing proclivities and the considerable amount of room they require. If neglect is added to these things, and the owner allows the plants to grow as they will, then Michaelmas daisies are far better left out of the calculations of the garden maker.

If properly cared for, however, these flowers—almost the last to bloom in the garden—will prove a valuable asset to even the small garden, providing as they do, with the chrysanthemum, helianthus and rudbeckia, a display in the autumn that no other plant gives.



MICHAELMAS DAISIES ALWAYS LOOK NEAT WHEN PROPERLY GROWN.

Where to plant is worth consideration. Never put Michaelmas daisies in the vicinity of less rampant subjects; keep them much to themselves. Plant them near to some object that will put a limit to root expansion in a backward direction—it is easy enough to control the front and sides. A brick wall is a good barrier; but do not plant them close up to the wall.

The next point is size. It may be a prevalent idea that the larger the clump the better the display. This is not so; as the illustration herewith shows. Six to twelve sturdy stems will produce a greater floral display than twenty or thirty strong and weak shoots mixed in a dense mass—the smaller stems should be removed early. It is a wise plan to take out deeply the central portion of each plant in alternate years, and fill the cavity with rich soil, and to divide the plants every third year, retaining the outside shoots only.

The final question of management is that of staking and tying. As soon as the plants are one foot in height, clear out the surplus shoots and tie those that remain each one to a 2ft. stake—thus will they grow straight. Later on, two or three tall stakes or canes may be added, and to these the tops of the stems may be secured just under the bunch of flower branches. Thus a neat, compact and columnar formation will be secured over which the mass of flowers will droop in lovely and artistic profusion.

Storing Dahlias.

THE dahlia is very tender and soon destroyed by frost. A good example of this tenderness has just been noted in one of the large London parks, where a magnificent bed of dahlias was blackened in a single night by a comparatively few degress of frost. The inexperienced amateur cultivator need not worry, however, if the leaves and top stems are blackened, because the tubers are at that time safe. But if the lower part of the stem is blackened, too, it may have a bad effect on the tubers. When the flowers have faded the grower should lift the plants and place them forthwith in a cool, dry shed. The stems should be cut off about 9ins. above the tubers and the name labels fastened securely to the top part of each tuber. Allow the tubers and any soil adhering to them just time to get dry—usually two days will be sufficient. In the meantime select the winter store quarters. There is no better place than a brick or stone-built shed where, having placed a thick pad of clean straw against the wall, the tubers can be arranged closely on the floor and then buried with fine, dry, sweet soil or sand. The final covering should be one of dry litter. Straw alone is not sufficient, as frost may penetrate, but it does not through straw and dry soil or sand. Boxes may be used, but they must be well covered in severe weather. Dry cellars are ideal places; in their case, too, dry sand should be packed round the tubers. It is important that air be excluded, then the tubers remain firm throughout the winter. In spring the cultivator expects to take cuttings from the tubers and, if the latter are stored in mouldy soil or under mouldy hay or straw, fungus grows and destroys the young shoots as they begin to grow.—G.

FLOWER GARDEN NOTES

A Pink Tree-Mallow.

LAVATERA OLBIA ROSEA is a rose pink form of the so-called tree-mallow. I have grown a considerable number of plants of it. It is a surprising thing to me that this subject is not more widely grown, particularly in gardens where space, or rather, lack of it, is not a matter of some consideration. In many gardens of all kinds which I have visited this year, the plant was, to all intents and purposes, unknown. I know of few plants or shrubs which have so long a period of flowering, and in circumstances where quick growth is desired few subjects can serve the purpose so well. Small plants some 12ins. or so in height when planted out in the spring become, in the course of a season's growth, large bushes some 5ft. tall and as much through, covered with blossoms. The plants start to flower quite early in the summer and continue to put forth new blossoms until the frost stops further growth.

A commendable point about this shrub is its tidiness; that is to say, the blossoms as they become spent simply die off and quickly wither away.

Lavatera Olbia rosea is not in the least particular as regards soil, and flourishes almost anywhere. I have in mind a fine belt of plants growing in what was virtually the edge of a gravel pit. The mass of colour thus produced was very effective indeed. I am inclined to think that the plant is rather more floriferous on soil of a gravelly nature than in one of a rich character. It is well to cut this lavatera back at the end of the flowering season.—H. C.

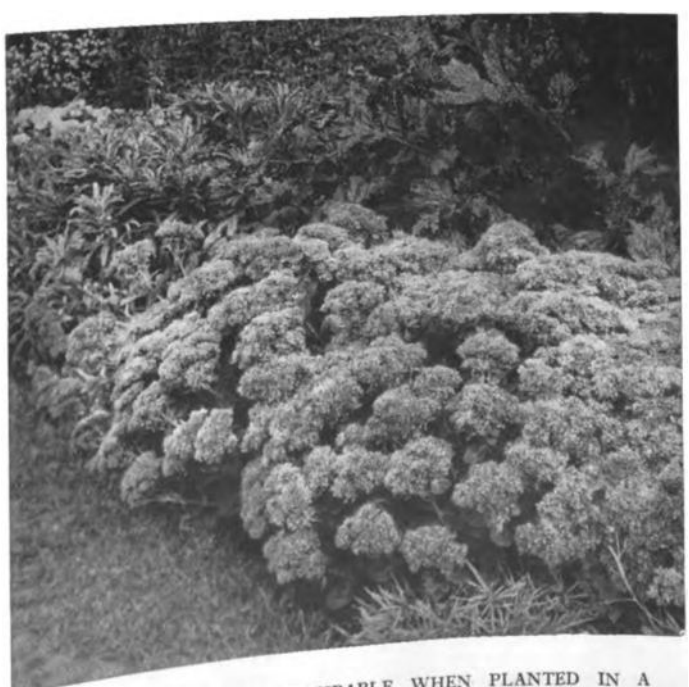
Moisture Loving Stonecrops.

ALTHOUGH the stonecrops, as a race, delight in dry, rocky places, a few must have a damp root-run if they are to be well grown. One of these is the late-flowering Sedum pulchellum. This beautiful species is never so happy as when at the brink of a pool or stream. In fact, it is so fond of moisture that Dr. R. Lloyd Praeger, the eminent authority on the genus, tells us he grows it in a pot plunged in a tub of water. The glaucous, linear leaves, often crimson-tipped, and the large inflorescences in rosy purple, of this stone-crop should be one of the most striking objects of our August-September gardens wherever the moist conditions essential to success can be afforded.

S. spectabile is one of those amiable long-suffering plants that will grow anywhere, but I have never seen it in such perfection as alongside a stream in a soil that is well drained yet always wet underneath. I have it, for example, where mimulus and Japanese irises flourish and there its enormous heads of a soft chalky pink, which go so well with the silvery sea-green of the foliage, make a magnificent show of colour throughout the later summer and autumn, and few flowers are more attractive to butterflies.

That much smaller species, S. ternatum, which produces a sparkling foam of white flowers in early summer, also delights in a cooler, damper soil than the majority of its race. The well known S. spathulifolium will do in the most arid conditions, but its fleshy rosettes do not, under such treatment, attain the size common to plants growing in better and damper soil nor do they bloom so well. On the other hand, those who are desirous of promoting leaf-colour in this charming species will probably find dry conditions more favourable.—A. T. J.

A ROSE PINK FORM OF THE TREE-MALLOW.



SEDUM SPECTABILE IS ADMIRABLE WHEN PLANTED IN A MOIST POSITION.

The Decorative Pyrethrums.

AMONG hardy perennials that bring a prodigality of flowers during late spring and early summer, pyrethrums occupy an important place in many gardens. Both single and double forms are worthy of culture when one takes into account the value of flowers for cutting. Rightly understood, they are plants an amateur can take in hand with every reasonable prospect of success, having long since established their right to be regarded as plants for a town garden. Pyrethrums do best when they are given a soil that is not too heavy nor too light, and this should be made rich by incorporating with it old rotted manure and decayed vegetable refuse. While some plant in autumn, there is a certain amount of risk attending it at this late period, and the wisest course to pursue is to do so in spring as new growth is pushing up. The position intended for them should be a sunny one, and between now and removal of the plants the ground should be got in good heart as suggested and left rough for a few months. Often one hears of pyrethrums dying off in winter, but most cases which have come under my observation have been due to their being planted in cold heavy soil, and in places that are badly drained. They are sun-lovers and give the best account of themselves when planted in warm positions. In the absence of manure, much can be done in improving the quality of the flowers by administering weak stimulants in liquid form and in spreading round the roots something that will conserve moisture—as leaves, for instance. The advantage of mulching is never more appreciated than if the summer be dry. Perhaps one of the most common mistakes amateurs are prone to make is to leave the clumps for several years without dividing them; but as they are rather quick in growth, it is unwise to put off taking them up and dividing after the second, or, in any case, the third year. Left to themselves, pyrethrums begin to degenerate in size of bloom, and though big flowers are not the aim, it is as well to avoid the opposite extreme, which must follow if division is neglected.

RAISING FROM SEED.

There is something to be said for raising pyrethrums from seed, which is comparatively easy; but the one who is bent on getting together a stock does not always realise that, among plants so raised, some will appear that vary little from those already in commerce; that really exceptionally good sorts are few and far between, and one must be prepared to wait a couple of years to distinguish which are actual prizes or otherwise.

Considering, however, that in most gardens not very many plants are wanted, it is, I think, more profitable to deal with a firm making pyrethrums something of a speciality, and select from their stock what one desires. The following varieties have proved worthy and may be safely relied upon:

Double.—Melton, crimson scarlet; White Aster; Empress Queen, blush pink; Ovid, rose; Aphrodite, white; M. Barral, crimson rose.

Single.—James Kelway, scarlet; Agnes Mary Kelway, rose pink; Mrs. Bateman Brown, crimson; Princess Marie, white; Hamlet, pink; Mrs. Langtry, flesh.—W. L.

ARE YOU PREPARING FOR NEXT YEAR'S ROCK GARDEN?

WHEN an open site has been chosen for the rock garden, and a plan marked out, however rough it may be, it will be necessary to excavate the soil at least a foot below the ground level. Where the subsoil is of a porous texture a foot will be ample, but if it is of a heavy, retentive nature, then it will be advisable to remove the soil to a depth of 18ins. When this is done the space is partly filled with clinker, small stones, or similar material, over which is placed a layer of turf, with the grass-side downwards. Where the position is low it may be expedient to put in a few land drains to carry off surplus water more quickly, for perhaps the most important factor in building a rock garden, however small, is thorough and efficient drainage.

This fact must be borne in mind throughout the period of construction, and if it is neglected at the beginning it cannot be remedied later on. Much, of course, will depend on the texture of the rocks and position of the site, and our object should be to see that the roots of the plants will be well supplied with moisture, and any water that the soil will not readily absorb can get away quickly. As the work proceeds and the rocks are set in position, further drainage can be added, but now it will be more in the way of small stones mixed with soil. No hard and fast rules can be laid down, but in forming a rock garden it can be noted the kind of plants which will eventually occupy certain stations and preparations made accordingly. Every pocket and crevice must be sufficiently drained, and this is accomplished by placing a liberal sprinkling of chippings with the compost in the crevices and pockets before the work is far advanced. When once the foundation of the rock garden has been laid so that the surplus water can get away without hindrance, there will be little difficulty in growing the great majority of alpines, providing due attention is paid to soil and position.

Various Soil Mixtures.

In a well constructed rock garden there will be a variety of positions for various alpines and these are known as pockets, chinks, crevices and fissures. Plants suitable for these positions and aspects can be selected, but after efficient drainage the next important thing is the rooting medium. In a short article it is not possible to deal with all the sections of plants for a rock garden and give their individual requirements, but much can be gleaned from a general survey of the usual mixtures employed. Pockets are made of different sizes and large enough to take several plants of the same kind, so as a rule a quantity of soil will be needed if the rock garden is a fairly extensive one. The soil best suited for the majority of alpines consists of ordinary loam three parts, and one part clean, wholesome leaf-mould, with a sprinkling of coarse sand, according to the texture of the loam. If the loam is poor in quality, then I would add a small portion of well decayed manure rubbed through a half-inch mesh sieve. That from an old mushroom bed is excellent, and a good substitute is a discarded hot bed. I often think that some of the more robust alpines are starved, and fail to give of their best because of an impoverished root run. Anything in the way of a clayey soil must be omitted, and good sharp river sand should be chosen whenever possible.

For plants enjoying a proportion of lime in the soil, a mixture of loam, leaf-mould, coarse sand and old mortar rubble in equal parts will be found useful. The lime rubble is obtained from any old dismantled building and it should be broken up and put through a quarter-inch mesh sieve. Another group of plants will not succeed if lime is present in the soil, and for these a mixture of peat, leaf-mould and sand is recommended. The peat is chopped up fairly fine and rubbed through a half-inch mesh sieve. Excepting for lime-hating plants I have little use for peat; it is poor stuff and if it remains in a sweet condition for any length of time it is always more or less dry, otherwise it absorbs much moisture and soon becomes a wet, sour mass in which no plants will thrive. A few plants will enjoy a mixture of good quality flaky leaf-soil and rough sand, such as Gentiana verna and similar subjects, and if a few small stones are judiciously placed between the plants the moisture will be retained and obviate the need for artificial water.

Although peat is not largely recommended, it is a necessity for placing in vertical fissures for such plants as ramondias and others that must be planted so that water will readily run off the crowns especially during the winter months. With some plants it may be expedient to add chippings, limestone or sandstone about the size of a filbert, but whatever is employed it should be thoroughly mixed together and be neither too wet nor dry when used.

The above mixtures I have used for the main or bulk of alpines, but with choice varieties, slight modifications have been made, and it has been found necessary occasionally to change the diet before the plant would succeed.

T. W. B.

MOST OF THE DIANTHUS FLOURISH WITH A SPRINKLING OF LIMESTONE CHIPPINGS ON THE SOIL SURFACE—

WHEREAS SUCH MOISTURE-LOVING PLANTS AS MANY PRIMULAS PREFER A SOIL WITH A LARGE PROPORTION OF HUMUS IN IT.

THE MAKING OF A SMALL ROSE GARDEN

Every reader of THE GARDEN *realises the importance of roses. Some may imagine that a small area is unsuited to the growing of this most popular of flowers. This article proves that this is not the case, and that roses will thrive exceedingly well in even the smallest garden.*

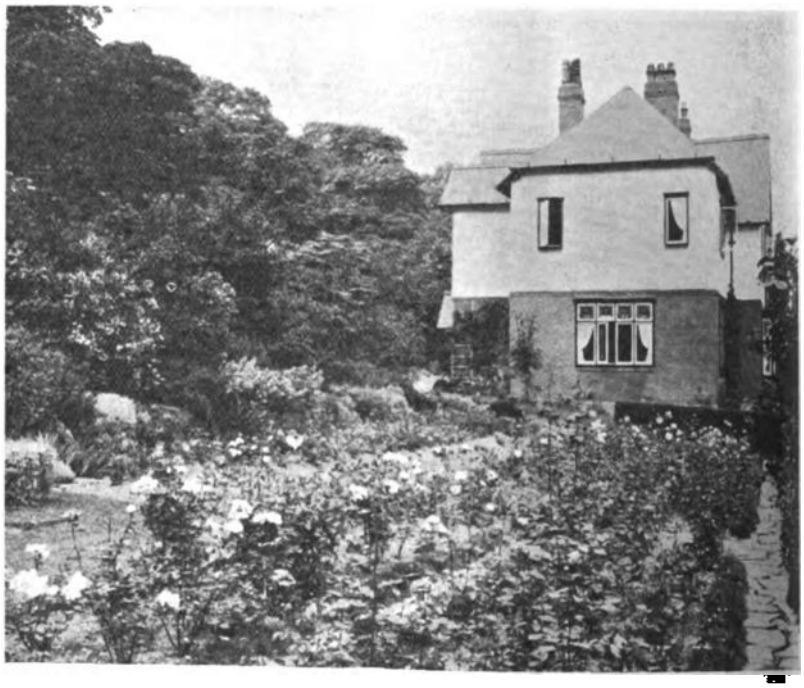
EVERYBODY loves roses, and everybody wants to do their best for the thing they love. Therefore all who have a garden wish to grow good roses in it. The setting aside of a part of their ground for the cultivation of roses, and such small plants as will associate with them, is, no doubt, the most satisfactory way from the point of view of the garden, as well as for the welfare of the rose.

The modern rose is so free-blooming, has such a long season of flowering, from June to November, its colours are so varied and brilliant, that it alone can furnish the space allotted to it with greater beauty than any other plant can do. If we are careful in our choice of varieties, we may add to the qualities already mentioned, loveliness of form in the individual rose, the finest of all scents, and abundance of foliage.

Up and down the country there are springing up countless small gardens, say of about quarter of an acre, and if their owners will make up their minds to spend a little money and a good deal of thought and work in selecting the best site and preparing the soil, there are few better places for a rose garden. For roses love new soil and they also love sunshine, and the majority of these gardens can give them both.

I once owned such a garden, on heavy, clay soil. We sacrificed a small lawn, too small to be really good for either tennis or croquet, and we cut our rose beds out of this lawn, digging out the soil 3ft. deep, putting in a drainpipe, then burning the clay, mixing it when it had turned to a sort of crumbling brick rubble, with the upper soil and with manure and leaf-mould and so refilling the bed.

In our present garden, high up on light gravelly soil, it is even more necessary than on the clay to dig out the bed fully 3ft. deep, to sift out the stones, keep the sifted soil for the top of the bed and get as much "top spit" dug from old pasture land as we can, chop it up and put it at the bottom of the bed and fill up with well rotted farmyard manure, if it is to be had, finishing with a surfacing of light, sifted soil.



A SMALL ROSE GARDEN IS ALWAYS EXCELLENT ON THE SOUTH SIDE OF A HOUSE.

In both these gardens we have grown good roses, but there is no doubt that on the lighter soil the plants require more manure and are less able to withstand a dry summer; they bloom, perhaps, more profusely, but the growth is not so strong, nor are the individual flowers so large as they are on the heavy Harrow clay. This experience has, however, taught us that given a fairly sunny site, not too windswept, roses can be well grown, whatever the natural soil of the locality may be.

WHERE SPACE IS AVAILABLE SOME OF THE GROUND SHOULD BE UTILISED FOR A SEPARATE ROSE GARDEN PLANNED IN A SEMI-FORMAL MANNER.

The Choice of a Site.

Make your rose garden, if possible, on the south side of your house. Though the borders round the house itself may afford a place for one or two climbing roses, they are not the best place for dwarf roses: they are apt to become too dry, and the roses grown in them seem peculiarly subject to green fly and mildew. This doubtless is because there is not a sufficient current of air. Moreover, especially in a small garden, one generally likes to keep these borders for early bulbs and wallflowers during the spring, and such sweet-scented, tender plants as tobacco plants, heliotropes, night-scented stock, mignonette and sweet alyssum, through the summer and early autumn.

Roses never look better than when surrounded with grass, therefore, if you have a small lawn, cut your beds or borders out of this. Those who prefer beds should make them round, oval, square or oblong, never in the shape of stars or crescents; each bed should, if possible, be planted with one variety, say of nine or twelve plants about 18ins. or 2ft. apart, according to the habit of the variety.

Borders of 5ft. or 6ft. wide, and as long as the ground will permit, with grass paths between of 3ft. or 4ft., look very well and are less trouble to keep in shape and need less time spent in mowing and edging. Three rows may be planted in a border 5ft. wide or four rows in a 6ft. border. These can be all easily reached for hoeing, pruning and general tending. In these borders the roses can be planted in groups of ten or twelve, the colours being carefully chosen in such a way that they add to one another's charm, that is to say, the soft pink of such roses as Caroline Testout should not be planted next to the brilliant cherry carmine of Betty Uprichard, or the terra cotta tints of Mme. Edouard Herriot, but should be separated

Digitized by Google

from them by some creamy variety, Mrs. David Mackee, Ophelia or Westfield Star. Almost all colours will associate with the deep crimson roses and none are more beautiful, though among the hybrid teas they are not so plentiful as they are among the old hybrid teas.

But the rosary in a small garden must consist principally of hybrid teas (and with these I include the so-called Pernet varieties), on account of their great freedom and continuity of bloom. In the heyday of the hybrid perpetual the month of August practically brought the rose season to an end, but, as I wrote at the beginning of this article, we can cut roses well into November. The polyantha pompons are also very free and continuous and make excellent little bedding roses, but where my space was limited I should keep the rosary proper for roses of finer form and scent. Should there be a small front garden, it may well be devoted to polyantha pompons and these make very neat, gay beds, taking the place of the ordinary bedding plants. If surrounded with an edging of some tufted viola of compact habit, Maggie Mott, Kitty Bell or White Swan, the beds will bloom from April to November. In the rosary, too, I would recommend edgings of violas. Nothing associates so well with roses and they revel in the rich soil.

Should it be desirable to divide the rosary from the rest of the garden, this may be done by means of dwarf hedges of the old pink China or the hybrid Bourbon Zéphirine Drouhin (one of the most fragrant of roses), trained horizontally. Or perhaps most charming of all, by the dwarf sweet briar. If taller hedges are needed, they may be formed of the hybrid rugosas or of the Penzance briars. If an evergreen hedge is wanted, nothing makes so beautiful a background for the brilliant tints of the roses as the dark, sombre yew. If this is used, it should be kept at some little distance from the rose beds, otherwise it will take too much of the nourishment provided for the roses. A beech hedge also is very attractive, with its soft, satiny green in spring and russet brown in autumn and winter. A series of interesting articles by Miss Jekyll on the making of small gardens has been appearing in THE GARDEN. Some of the designs suggested might be adapted for rose gardens.

Question of Cost.

It is difficult to estimate exactly the cost of making such a garden. The labour will be the first item and there is a good deal of labour in digging out and preparing soil, wheeling it away and wheeling in the compost which is to fill the beds. A jobbing gardener's wages in the neighbourhood of London would probably be about 10s. a day. Manure is expensive, 10s. to 12s. a load, and, moreover, it is hard to come by. Of course many artificial manures, such as Wakeley's Hop Manure, are excellent substitutes for ordinary manure. "Top spit," the most important ingredient of all, costs anything from 10s. to 15s. per load and may often be obtained locally where building is in progress.

For the fortunate people who live on a loamy soil, much of this labour and expense is unnecessary, but even they must see to it that the rose beds or borders are properly drained for roses dislike stagnant moisture at their roots.

As regards the plants themselves, the average cost is 1s. 6d. for the older and 2s. 6d. to 5s. for the newer varieties. These prices are for dwarf budded plants, from English nurserymen, and it is always worth while to buy British plants; they may cost a little more than the Dutch plants in the first instance, but they are far more satisfactory in the long run.

Suitable Varieties.

In conclusion I give a list of well tried hybrid tea varieties which have grown and flowered freely in my own garden and which have the right habit for grouping in beds and borders. I shall not include any single-flowered varieties, such as K. of K. or Isobel, because, lovely as they are, their blossoms are fleeting and in a small collection the roses with more staying power are preferable. On the other hand, I am omitting purely exhibition varieties, however exquisite their individual blooms may be. Though in varying degree all roses in this list have some fragrance, I will start with the crimsons, for the rose of roses is a red rose.

Crimson.—General McArthur, Etoile de Hollande, Mrs. Edward Powell, Richmond, C. E. van Rossem, Hortulanus Budde.

Pinks and Salmon Pinks.—Caroline Testout, C. E. Shea, Mrs. Henry Bowles, Mme. Butterfly.

Flesh Colour.—Mme. Léon Pain, Ophelia.

Coppery and Terra Cotta Shades.—Lady Pirrie, Mme. Edouard Herriot, Henrietta, Padre.

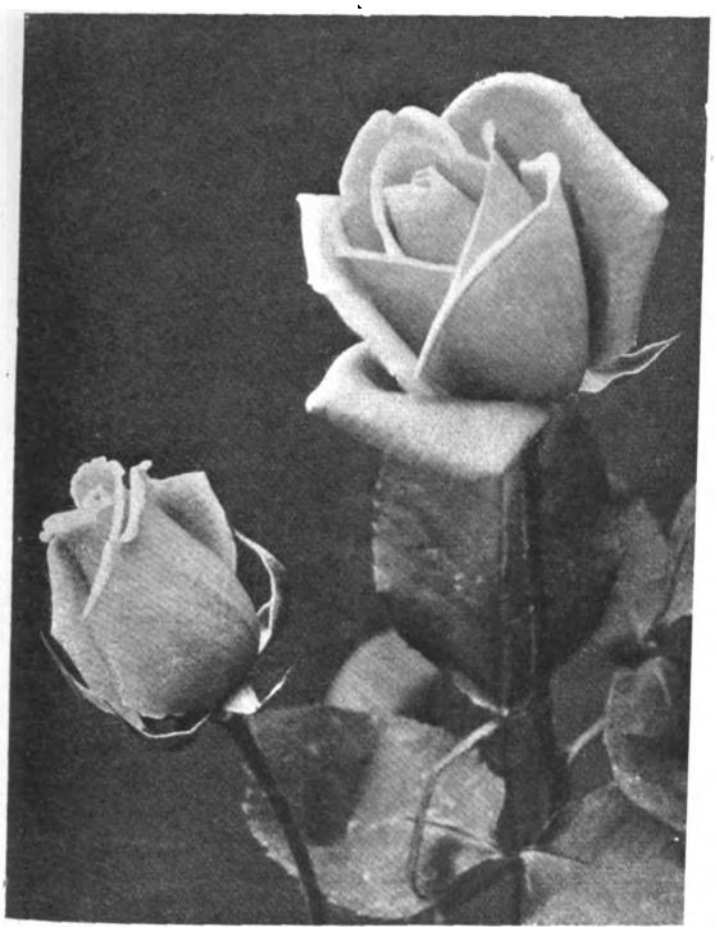
Cerise.—Betty Uprichard, Lady Inchiquin.

Apricot.—Los Angeles, W. F. Dreer.

Yellow and Orange.—Independence Day, Mabel Morse, Mrs. Dunlop Best.

White and Cream.—Marcia Stanhope, Mrs. David Mackie, Westfield Star, Mme. Jules Bouche.

WHITE LADY.



THE CLEAR PINK CHARLES E. SHEA.

INDEPENDENCE DAY, GOLDEN BLOOMS SHADED WITH APRICOT.

ECONOMICAL GREENHOUSE HEATING

Although no heating apparatus equals the boiler and pipe system adopted in most modern greenhouses, yet there are many other simple devices which can be made use of by the amateur to heat the greenhouse. This article which gives a few hints on how to conserve heat and utilise fuel to the best advantage should prove invaluable to all readers.

In the Heated Greenhouse.

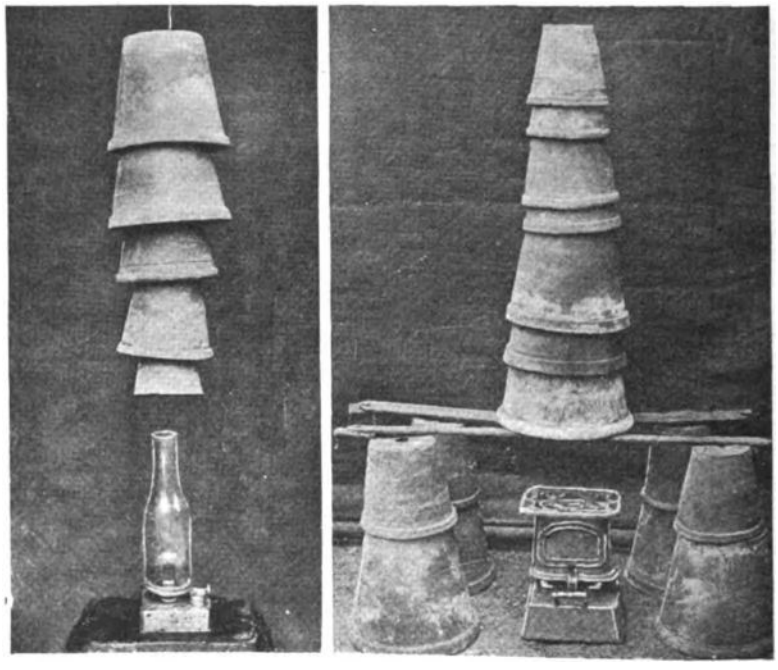
DURING the past few years the question of heating of our greenhouses and other plant structures has been a very serious one. Through the coming winter and spring the need for economy will be as great as at any time in recent years. After growing choice plants through the summer months and others for many years past, it may be, the cultivator does not like to lose them suddenly. The management of large boilers will be dealt with first. If the pipes have been properly arranged, there will be valves in the right place in every house. It may be that some houses—such as vineries and peach structures—can be left cold until next March. That being so, odd plants, now in them, should be taken to other houses and these should be filled, but not overcrowded. Thus the heat can be turned off the vineries and peach houses and confined to the others and so save fuel.

Except when there is actual frost, there will be no need to maintain a high temperature during the daytime in open weather, but the fire need not be drawn. The following routine work should be observed. Early in the morning open dampers and ashpit doors; put on a shovelful of fuel, in twenty minutes time the fire will be brighter and it is at this stage that all the ashes can be worked through the bars without putting out the fire, as might be the case if they were violently raked out the first thing. Then add a little more fuel, keep on full draught, directly the fire is again bright, feed with a certain quantity of dry fuel and finish with two shovelfuls of damped slack; regulate dampers. The fire, so treated, will ensure the pipes being nicely warmed throughout the day and not require any more fuel to maintain the heat. At sunset open out the fire again and get the pipes warm enough to ensure the temperature being at its maximum by nine o'clock, when, on a bright, flat-shaped fire place dry fuel and finish with wet slack. Give full draught for twenty minutes or so, then regulate dampers and ash-pit doors for the night. The heat in the pipes can be regulated by manipulating the valves to ensure the right temperatures for exotic plants and those for common greenhouse subjects. By bad management as much fuel may be burned in four days as would suffice for seven and maintain better temperatures where careful stoking was the rule.

In Small Houses.

SMALL glass structures are much more difficult to heat than large ones. Many pipes connected with a large boiler maintain the heat in a big house much more evenly than a few connected with a small boiler do in a small house. In the latter the heat soon rises to 80°; it also soon falls to 40° in cold weather if the boiler is "driven" or allowed to cool over a dust-choked fire.

Now, it is the small greenhouse, its pipes and boiler, on which it is desired to give a few hints. The slow combustion stoves or furnaces will consume coal, coke, cinders, slack and even ashes. A combination of these will prove very economical. The boilers are, mostly, fixed in the brick wall but without any brickwork to form flues, etc., as is the case with plain saddle and check-end saddle boilers. The boiler, being inside the greenhouse, emits heat equal to 6ft. to 10ft. of piping. It is always wise to light the fire or open dampers to allow a slow one to burn up again quite one hour before sunset so that the pipes will be warm by that time, thus preventing condensation of moisture on any blooms that are open in the house. Not only should heating be done with a view to warming the house, but also with that of driving out excessive moisture through the slightly opened top ventilators. When starting the fire do so properly, get a good hot glow as soon as possible, it is economical to do so; get heat from every ounce of fuel; a dull, slow fire consumes or spoils fuel without generating any appreciable heat on the boiler's surface. When the heat is approaching the maximum regulate the fire carefully. Do not choke the furnace with fuel at any time; a small quantity of fuel when it is required evenly spread out on the fire will soon cause the free circulation of water in the pipes. Always "bank-up" at night when the fire is bright, and use damp slack or ashes as a top thin layer on it. One part coal and slack to two parts well broken coke combine to form a good heat-engendering fuel. Ashes and rubbish fuel should, generally, be used when the fire is being driven a little, then it will all be consumed. If such be placed on a slow fire the latter will be put out, or nearly so, certainly it will be choked. Keep the ash-pit empty.



A SIMPLE DEVICE FOR HEATING THE GREENHOUSE.

When You Cannot Heat With Coal.

COAL, and coke too, are not only difficult to get at the present time, but they are also very expensive. Of course, until the weather becomes very severe, many tender plants in the greenhouse may be protected to an extent without the use of artificial heat. The old-fashioned plan of spreading newspapers over the specimens is not by any means to be despised. Then, in the unheated house, risk of damage by frost will be minimised if attention is paid to a few special points. Keep the soil in the pots very much on the dry side, as, in cold weather, all plants suffer much more if their roots are in damp earth. Keep the house as airy as possible. Although there may be a frost at night, there are usually some hours round about midday when it is quite mild, and then ventilation should be freely allowed. Where the air remains in a stagnant state in a house, it tends to become damp and chilled, and should a frost occur much greater harm will be done to the plants.

Sooner or later, however, there comes a time when, in the case of many delicate subjects, some kind of heat is essential if damage and loss are to be avoided. Stoves heated by paraffin oil lamps will, if carefully used, help much to tide one over the time of difficulty. In a small greenhouse or a conservatory, emergency oil heaters are not difficult to fix up. One which the writer has found really useful is formed of a large lamp and four flower-pots of varying size. The biggest of these pots might be about 14ins. in diameter, the next 12ins., and the remaining two 10ins. and 8ins. Thus, when in an inverted position the pots can be fitted one above the other. The lamp is placed on the floor, and, on either side, bricks are arranged. The large pot is placed over the lamp and the others are piled up above it. It is a good plan to have a tin tray of water on the pot that is uppermost to prevent the heat from being too dry. This arrangement will give out quite a fair amount of heat that will serve to keep the frost at bay. Another plan is carried out with a stove of the well known "Beatrice" type. Here a large biscuit tin is filled with sand and placed on the top of the stove. The sand is all the better if it is kept moist as far as possible. In some cases it might be worth while buying one or other of the excellent oil heaters that are specially made for greenhouses. The best of these are fitted with a hot-water system and, being portable, they can be moved to any part of the house where warmth is specially needed.

Fumes from lamps do not seem specially harmful to plants, *always providing the burners are kept clean.* It is an excellent plan to boil all lamp burners in a hot soda solution once a week. Then, each day, run a cloth over the wicks to remove the black crust that has formed. When once a wick has been found to burn with a regular flame it will not require any further trimming with scissors. It is most important to take precautions against smoking. A few hours of a smoky lamp in a greenhouse will do a very great deal of damage. Lamp flames tend to go up slightly half an hour or so after lighting, and, on this account, it is a good plan to turn the wick somewhat lower than its best before leaving it for the night.

THE FRUIT AND KITCHEN GARDEN

Planting Currants and Gooseberries.

THE earlier the planting of currants, both red, white and black, is carried out the better. In this way new roots are formed at once, and, if the bushes are of good size, there will be every reason for expecting a crop in the following season. Currants are vigorous plants, likely to produce large quantities of roots and, on this account, they do best in good, rich loam, 2ft. or more in depth and rather on the heavy side. The bush form is invariably adopted in the case of black currants and also for the chief crop of the red and white kinds. A space of from 5ft. to 6ft. should be allowed between the bushes in open quarters. In a district where the soil is very light, positions with a south aspect should be avoided, as here there is a great risk that the fruit will shrivel or ripen prematurely and, in any case, it is likely to be inferior to that from bushes grown in more shaded localities. Red and white currants are often grown on walls with a northerly aspect. In such situations the crop will hang until November, but it cannot, of course, be expected to have the flavour of that more exposed to the sun. Bush currants are sometimes planted alternately with pyramid apple or pear trees by the sides of walks; currants that have been trained as pyramids are particularly well adapted for such positions.

GOOSEBERRIES.

Gooseberries thrive in any good garden soil, but this should, preferably, be of rather moist nature. For growing really fine fruit there is nothing to equal a rich loamy soil which has been deeply dug and enriched with well decayed manure. One cannot well have the situation too open for gooseberries, and where the position is even slightly shaded the fruit is nearly always inferior in size and flavour. In planting the bushes a distance of 5ft. should be allowed between each, and there is no harm in using the intervening space for some other crops until the gooseberries become established. As has been described with currants, late crops of gooseberries may be secured by planting against a north wall. The bushes may be set out in the ordinary way or, if desired, the shoots can be trained against a wall. When employed to cover a north wall the fan system of training may be adopted, or the plants can be inserted when young 9ins. apart and three perpendicular shoots conducted from each at equal distances. Gooseberries grown on north walls, although late in ripening, often provide a more reliable crop than is secured from the bushes in the open. In the bleaker parts of the country this plan is not to be recommended, and here the gooseberry bushes should be given full exposure to the south.

THE SOIL.

The soil should be on the dryish side, as it is then more easily worked. On no account should planting be done when the ground is wet and sticky. At such times it is best to defer the actual planting and to "heel" the bushes in until the conditions improve. Of course, there may come a time when planting simply has to be done, whatever the state of the soil. Here it is really a good plan to dig the holes out two or three days ahead of the actual planting, breaking up the bottom of the opening well and passing the removed soil through the fork as often as possible. Plant to the depth of the soil mark on the main stems of the bushes and spread the roots out thoroughly. Sprinkle a thin layer of soil lightly over the roots and finish by treading in the final covering. As a rule bushes of currants and gooseberries do not require any staking. It is well, however, to watch the bushes and, if these show signs of being unduly blown about, some support should be given.

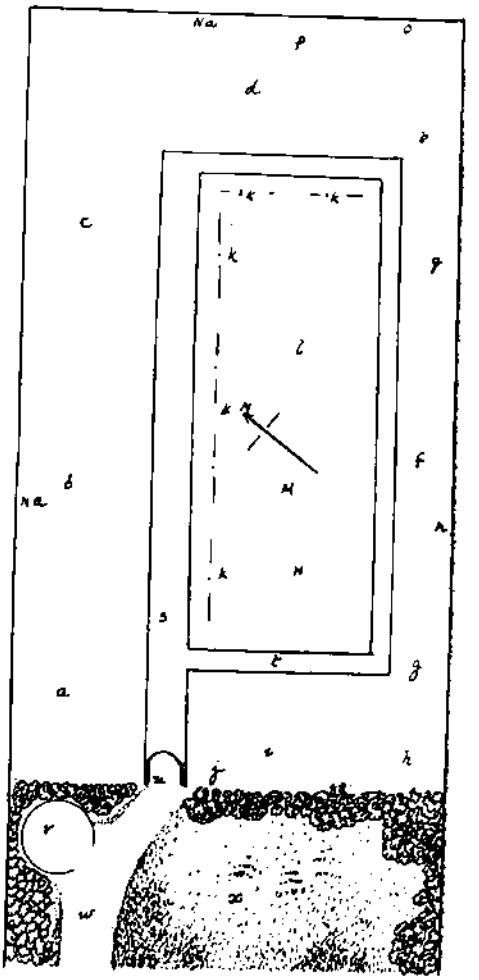
Lettuce and Parsley.

IT is never a difficult matter to get lettuce plants safely transplanted in the spring if we leave out the trouble arising from slug attacks. In the autumn, if the weather is very dry and cold, the most successful way is to transplant lettuces on slightly raised ridges on a very warm—a south aspect—border or at the foot of a wall. It is excessive moisture that does the most harm in winter. In convenient places the plants can be temporarily covered in very frosty weather. The soil should be rich, deep and firm. Winter parsley is valuable. Many cultivators, no doubt, found it difficult to raise July seedlings owing to the dry weather. But if plants are scarce, thin out the available seedlings to 9ins. apart and transplant the spare specimens in a sheltered border now.

The Small Fruit Garden.

HOW TO ARRANGE IT TO THE BEST ADVANTAGE.

CERTAIN kinds of fruits may be grown more extensively than others according to the requirements. The plan shows how a small garden may be planted to the best advantage with a representative collection; a few trees of each, some in warm positions and others in cool ones to prolong the supply as much as possible. Espaliers are provided for on the south side of the broad path so that their shadow will be cast on the path and not on any valuable border space. *a* shows black currants; *b*, gooseberries; *c*, early strawberries; *d*, early raspberries; *e*, late raspberries; *f*, late black currants; *g*, a medlar; *h*, a mulberry; *i*, late strawberries; *k*, *k*, *k*, *k*, *k*, espalier pears; *l*, apples



(bush-shaped); *m*, white currants; *n*, red currants; *na*, *na*, pears; *o*, plums; *p*, loganberries; *q*, cherries; *r*, late plums; *s*, broad path in front of warm early border; *t*, narrow paths to economise space; *u*, arch; *v*, summer-house in flower-garden portion; *w*, path leading from dwelling-house to the fruit garden; *x*, lawn.

Storing Fruit.

THIS has been a good pear season, and it is worth while to keep the fruits under proper conditions. Do not pile the fruits one on the other just anyhow, place them upon a shelf that is perfectly dry and likely to remain so. The atmosphere of the storing place should be decidedly cool and airy, frost and damp proof; a warm, close atmosphere is fatal.

Again, the fruits need *air* all around them, and when lying upon the wooden shelf quite a third of the fruit gets no air and is liable to decay. Placing the apples or pears upon a thin layer of clean, dry straw—not hay—ensures the admission of air to the undersides of the fruits. No apple or pear should touch its neighbour. By this method the fruits will keep sound and juicy without any suspicion of decay until they shrivel up with old age.

The late-maturing kinds of apples, and those pears that have to be gathered while still in a hard state, can be kept well into the spring under these conditions.

APPLES STORED ON STRAW ON A SHELF.

WHAT OUR READERS SAY

SOWING SEEDS OF PRIMULAS.

Candelabra and Sikkimensis sections.

SIR,—If success is to be attained in the propagation of these most useful sections of primula, the most important factor to bear in mind is that the genus as a whole loves moisture, particularly the sections mentioned. Included are the following:

(*a*) *Candelabra Section.*—Yellow flowers—P. Bulleyana, P. Cockburniana, P. serratifolia, P. helodoxa; purple flowers—P. Beesiana, P. glycosma, P. Poissonii, P. pulverulenta, P. Wilsoni.

(*b*) *Sikkimensis Section.*—Yellow flowers—P. sikkimensis, P. microdonta, P. Florindæ; purple flowers, P. secundiflora, P. vittata, P. microdonta violacea.

Where large numbers of young plants are required and space is limited, the old system of sowing in pot and pan can be discarded and the more up-to-date and easy method adopted that of sowing in a cold frame. Bearing in mind that moisture plays a very important part in the germination of seeds and after-growth of the young plants, it is necessary that a layer of some moisture-retaining substance should be included in the preparation of the frame. Above the drainage, sphagnum moss or well rotted manure, preferably the latter, as it will be of use when the roots penetrate to that depth, should be placed to a depth of 6ins. A compost consisting of loam, leaf-soil and sand, is added 4ins. to 5ins. deep, the level of which should be about 6ins. from the glass at the front of the frame. Two methods may be adopted for sowing seeds: (1) In drills; or (2) broadcast; but it should be borne in mind that, in whichever way, the seeds must be sown thinly and evenly, otherwise the young plants will be drawn and have a tendency to damp off. The covering should be of the lightest possible, the golden rule for all seeds being that they should be covered to their own depth. Watering must be done with a fine rose to prevent washing away the seeds, and the frame should be kept closed until germination takes place. Seeds may be sown now or in the spring.—A. McC.

THE DECORATIVE MICHAELMAS DAISY.

SIR,—I am sending an illustration of my Michaelmas daisies, Nancy Ballard, which may be of interest to readers of your very valuable paper THE GARDEN. The asters have been, and are still, a very wonderful display, and are very valuable at this season. The flowers are large, compact and clear, and provide the most charming decorative effects in the garden.—(Mrs.) E. A. BROOMHEAD, *Aylesbury, Bucks.*

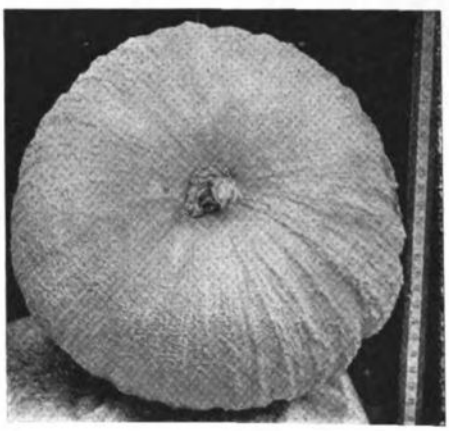
ASTER NANCY BALLARD IN A READER'S GARDEN.

HOW TO KEEP PLANT LABELS READABLE.

SIR,—On page 589 "N. D." gives a good way of keeping wood labels legible, but wood labels rot. The late secretary of the Royal Horticultural Society (Mr. W. R. Dykes) told me what he found most satisfactory was a zinc label with about 1in. of the top bent over at a right angle and the name or a number written on the upper surface and varnished. The label could not rot or sink in the ground out of sight, and ever since I have used zinc labels in that way.—V. C.

A RECORD PUMPKIN.

SIR,—We send herewith an illustration of a record pumpkin grown by one of our customers, which is exhibited in our Regent Street Garden Shop.



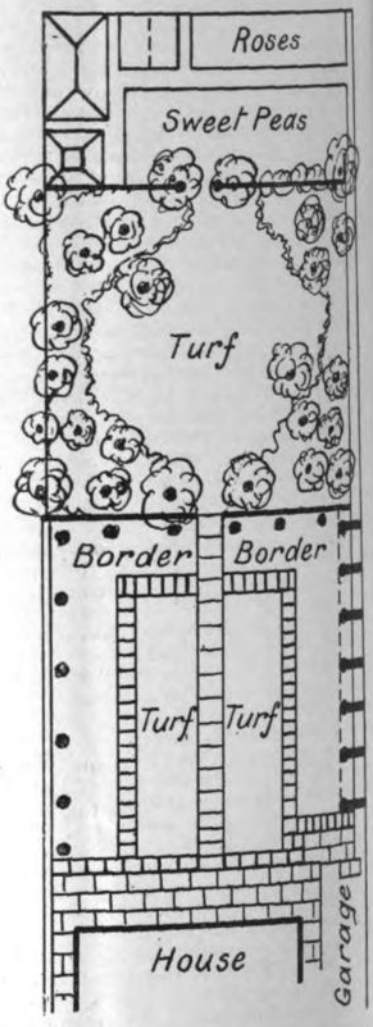
A MAMMOTH PUMPKIN.

The extraordinary weight and measurement are as follows, weight 114lbs.; girth, 74ins.—JAMES CARTER AND CO.

THE JOY OF MAKING A NEW GARDEN.

SIR,—As you ask for reader's ideas on garden-planning, I venture to send you an alternative suggestion for the back garden planned by Miss Jekyll on page 551. Miss Jekyll's designs have always been beyond criticism to me, but this particular one I find, as an ardent flower-lover, a little too utilitarian. Personally, with a comparatively small area at my disposal, I would sacrifice the remainder of the fruit left me by the birds and the bacterial pests for flowers most of the year. Also, being a keen badminton player, I could not devote to what is *not* an outdoor game in England a piece of otherwise invaluable ground quite inadequate in size for any serious attempt to play the game when I might have bulbs and flowering shrubs and green grass to charm my eye.

I should divide the ground as shown in the sketch, shielding the service path to the north with a pergola of natural wood covered with climbing plants and roses, as far as the junction of glade and sunk garden. The "mounds" should help to raise the borders round the little formal garden, a cupressus hedge forming an evergreen background to the border plants; while the adjoining 50ft. of ground should be laid out as a little grassy glade planted with groups of flowering shrubs and such



apple trees giving profusion of blossom in spring and brightly coloured fruit in autumn, and as many bulbs in as many varieties as could be squeezed in.

The remaining 25ft. would be devoted to a small cold house, two frames, a small shed, and all the rest to roses and sweet peas for cutting, with perhaps a couple of rows of edible peas and small salading—if room could be spared!

The dry walling round the borders would be bright with rock plants in their season, and the wide turf borders and paved path leading to the glade should give dignity to the view from the house. The borders must be carefully planted for profusion of flowers from June to October, so that there might be something of interest somewhere all the year round (even though it be æsthetic and not gastronomical!).—C. E. A.

ORCHIDS FOR AMATEURS.

SIR,—I often wonder why more orchids are not grown by small amateur gardeners, having just seen a group in a small house full of flower of the "Lady's Slipper," Cypripedium insigne. I can assure all those with small houses, that they are as easily grown as "geraniums," in fact, they need hardly any attention. I have a small batch of plants that were potted in small pieces of

Digitized by Google

pot broken up with moss, mixed with a part of rough turf two years ago. They are at present in bud and will last until nearly the end of the year. Watering has not been carried out as it should be and as for diseases I find they are immune. During the great war the house had no heat and very little attention, so growers need not be afraid of the "coal bill."

As a cut flower they will last in water for nearly three weeks. So I am writing to persuade readers of THE GARDEN to buy a plant and see if they can kill it with fair treatment. I believe there are other hybrids well worth growing, such as C. Maudiæ.—H. M. B.

SHRUBS FOR THE SMALL GARDEN

SMALL berried shrubs for autumn colour are often a problem in the average garden where many of the berberis and cotoneasters grow to too large a size. One, however, that is eminently satisfactory is Pernettya mucronata, so long as the soil is free from lime and is fairly moist. It is a stiff, dwarf-growing evergreen with tiny white flowers that are followed early in autumn by deep purple berries. As it rarely grows more than 3ft. in height, it will be seen how valuable this plant is. Various hybrids also exist with white, pink and red berries.

The philadelphus, or mock orange, is so important for its free-flowering qualities that no one can afford to leave it out of the garden, even though it grows into a big bush. Still, with care taken in its placing, it is a most suitable and charming shrub for all gardens. It can be grown as a corner plant where size is not a matter of the greatest importance. It is, however, too coarse a grower for the middle of a herbaceous border. Remember that it is not so much the height of a well grown specimen that counts but its girth and the spread of its crown. The modern hybrids are vast improvements on the older species. Two that can be thoroughly recommended are Virginal, a vigorous grower with large, fragrant, white flowers, and Boule d'Argent, a free-flowering double white.

One of the most important shrubs for all gardens is the shrubby cinquefoil, or Potentilla fruticosa, and its varieties. Why this useful late summer and early autumn flowering shrub is not universally popular is beyond comprehension. It is free-flowering over a long period when few shrubs are in flower; it is absolutely hardy; it is a neat grower up to 3ft. in height; its saucer-shaped flowers are most attractive. All forms are good, most of them a clear lemon to butter yellow, and one is white, Potentilla Veitchii. They require no attention beyond the cutting out of some of the old wood each year.

Flowering cherries and flowering crab apples are always a problem. Their number is now legion. The choice is largely a matter of space available, and if in doubt it is always as well to see a full-grown specimen in a nursery or at Kew before making your choice, as it is a pity to plant a fine variety that has to be hacked out in a few years because it is too large. Where small trees can be grown, it is probable that the two most useful species are Prunus Pissardii with its dark coppery foliage and pink flowers and Pyrus floribunda and its variety atrosanguinea, the former with pink flowers and darker buds, the latter of a deep red.

A FINE FLOWERING SPECIMEN OF PRUNUS PISSARDII.

A close relative of the thorn is the pyracantha, and here we have another excellent suggestion for wall shrubs. They are evergreen and neat in growth, while they are among the most brilliant berried shrubs that we possess. The two best for ordinary purposes are undoubtedly Pyracantha angustifolia with large clusters of orange yellow berries and Lalandei with fruit that is almost an orange-scarlet. Provided that the soil is fairly deep, they will thrive under almost any conditions if given the shelter of a wall.

For a piece of waste ground where the soil is poor there is nothing to equal the flowering currant, Ribes sanguineum. The importance of this remarkable flowering shrub is hardly realised, although it has been in cultivation for over a century. It grows too large for the border or garden proper, but it is so hardy, so floriferous and of such easy growth that it is admirable for ground that may otherwise be difficult to fill. It is particularly suited to the East Coast, where year after year it will make a gay show in April with its various tints of red according to variety.

One of the unique shrub effects in the garden is gained by a small group of the lavender cotton, Santolina chamæcyparissus, which is so attractive owing to its greyish white foliage and its round balls of yellow flowers. As it never exceeds 2ft. in height, it is useful as a foreground shrub. If anything it prefers dry poor soil where it can get a maximum of sun, and for this reason it is valuable where other plants may not grow. It flowers profusely in July. Another plant that has no objection to dry conditions, although it should not be planted in full sun, is the skimmia, which is rather like a laurel in its foliage, but has pleasant little white flowers and usually bears a fine crop of scarlet berries. They are, in fact, like an improved and dwarfer laurel, and for this reason are useful in small gardens for many purposes for which the laurel is too coarse a grower. The best species are Skimmia Fortunei and S. japonica with rather larger leaves. Both have fragrant flowers.

The spiræa and the lilac are so important and such large groups that they will have special notes to themselves in a following issue. Although the viburnums as a whole are too large for the small garden, yet there are one or two that are so important that they cannot be left out of a list of suitable shrubs. The first is the snowball tree, the sterile form of our ordinary guelder rose. This is not only valuable for its masses of creamy white flowers in summer, but the leaves are often well coloured in autumn.

Last of all is the wistaria, probably the finest climbing plant in the world, with its long racemes of mauve-lilac flowers that are produced so freely during early summer. For porches or pergolas, or even trained over an iron umbrella, there is hardly a plant to touch it. It is better for being planted in a sunny position, but on no account must it be allowed to suffer from drought.

The only plant which can approach it is the Sweet Water Vine, which looks so effective when draping an iron or, better still, a wooden support or bracket in the house wall.

Nothing could be of more simple culture, and its beauty in autumn with its rich colourings will well repay its inclusion. E. C.

THE BRILLIANT BERRIES OF PERNETTYA MUCRONATA.

HINTS WORTH REMEMBERING

This is a further instalment of Hints that have been received from our readers in response to our request. There seems little doubt, judging from the numbers that have reached us, that this will prove a most useful feature of THE GARDEN *in future. We hope, therefore, that all our readers will assist to make this page as valuable as possible by sending in their Hints, the result of personal observation and trial, and so help the gardening public in general. Hints which will be specially considered as worthy of a prize will be those that are seasonable as well as interesting and apply particularly to duties that can be carried out in the garden at the present time.*

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Each must be sent in on a separate sheet and must not be more than 300 words in length.

THE HALF GUINEA HINT.

A Good Method of Growing Asters.

In using perennial asters as a background for herbaceous borders which cannot be deeply cultivated year by year, I have found the following method both successful and economical: Being gross feeders and well doers, when properly grown they need yearly division. Each autumn the old roots are dug up and holes 15ins. square and 1ft. deep are opened out on the same sites, and two spadefuls of good rotten manure placed at the bottom. The old soil is used to fill up the holes and three single crowns from the old root planted in the form of a triangle. So treated the young crowns will produce in the following season strong branching stems, sometimes as thick as a forefinger and carrying a multitude of perfect blooms.—S. H.

A Remedy for Woolly Aphis.

At this time of the year, when the summer pruning is finished, this pest is easily seen on any apple trees subject to an attack. Various remedies have been suggested by fruit-growers, but I have found none so effectual as the following mixture: Mix two-thirds of paraffin with one-third of creosote, or Stockholm tar, and apply this to the infected parts with an ordinary paint brush. The young wood should be only lightly brushed, but old wood may be more heavily painted, where the aphis is in crevices. This not only kills the insects, but heals the wounds, and appears to prevent any future attack in the same parts.—F. I. L.

Propagation of Greenhouse Chrysanthemums.

In November, December and January, as blooms fade, remove from pots and plant in reserved sheltered space in kitchen garden. In April, dig up roots, tear off the side shoots. Each a well rooted plant. Place in nursery bed, stop as necessary, in September pot up, and after three weeks put in a greenhouse. This well proved method resulted in hardy well shaped plants, of perfect foliage, with blooms of exhibition size, with the minimum of labour. This method evoked the commendation of the late Rev. W. Wilks, President of the R.H.S.

The ordinary method of detaching and inserting in sand in greenhouse is in no manner comparable, involving considerably more attention, with far less satisfactory results.—E. M. W.

A Home-Made Garden Frame.

It might interest your readers to know how a very useful and cheap three-light lean-to garden frame can be made, using breeze blocks for the sides and divisions (3in. blocks, 36ins. by 12ins., can be cut with cold chisel), joining the blocks with a mixture of cement and sand (about 1 to 3), small deep holes made near the edges of each block to take clamps made of strong wire, cemented in. The pieces of 3in. by 1in. wood, to form the frame, are bedded in cement mixture and nailed on to the breeze. Brush over inside and out with a thick, creamy coat of cement mixture. Paint all woodwork. Three glazed garden lights bought from a much-advertising firm complete an excellent and lasting job. This frame is used for propagating plants, has to be always kept wet, and is, therefore, superior to one with wooden sides.—E. T.

Thalictrum dipterocarpum.

This seems to be a rather difficult plant to grow successfully. I had a batch of these under my charge in a Gloucestershire garden which everybody admired who saw them. The tallest plant reached a height of 6ft. I examined the border afterwards to see what the subsoil was, and found that it was nothing but brick-ends and mortar rubble. The top soil, which was only 10ins. or 12ins. deep, was enriched with cow manure.—F. W. D.

To Prevent the Ravages of Sawfly Caterpillars on Gooseberries.

In the spring sow broad beans at intervals of about 18ins. to 2ft. apart between all the gooseberry bushes. I have never yet known this preventive measure to fail.—C. E. W.

Storing of Onions.

To prolong the keeping of onion bulbs place them in a moderately hot oven for a few hours until the outer scale leaves become quite brittle. When thoroughly dry they should be stored in a wire netting cage, suspended from the roof of an outhouse to allow a good circulation of air to pass freely among the bulbs.—S. G.

NURSERIES OF THE BRITISH ISLES.—VI

MESSRS. LAXTON BROTHERS, BEDFORD.

THE UNFADABLE AND FRAGRANT ROSE BEDFORD CRIMSON.

THERE is a well known saying that an army marches on its stomach—in the same way, a garden to prove itself to be something more than a fleeting thing of beauty must have a solid foundation of fruit and vegetables at the back of it. This is particularly necessary in these days, when even the most ornamental things should have something of economic value behind them. There are many fruits and vegetables on which gardeners of the British Isles can pride themselves, among them strawberries and peas, and for the introduction of many of the most noted varieties of both of them we have to thank the firm of Laxton Brothers of Bedford.

Experiments with Peas.

It is not generally known that Mr. Thomas Laxton, the father of the present head of the firm, began experimenting in plant breeding almost simultaneously with the famous Mendel. So long ago as 1858 he started breeding the garden pea and carried out several experiments at the suggestion of Charles Darwin. An early experiment was crossing a round white early with a tall Maple, or coloured field pea. Actually it has been proved that in 1867 he was independently recording similar work to that being done by Mendel. The first certificate granted him was in 1865 for his pea "Supreme," the origin of the famous Telephone class. Between that date and his death in 1893, numerous

THE VEITCHBERRY

(NEW HYBRID FRUIT)

Raised by crossing the November Abundance Raspberry by a Blackberry

This new Hybrid Berry we claim to be the best of all the berries yet raised. The fruit is the colour of a well-ripened Mulberry—about twice the size of an ordinary Blackberry or Raspberry. The flavour is delicious. The fruit is sweet and has the combined flavour of the Raspberry and the Blackberry. The one great advantage of this berry is that it is self-fertile, and sets all its fruits perfectly—and it does not need to be planted near any other berry to cross-pollinate it. It is a strong grower, semi-erect, and needs only a stake to support it. It can also be trained on a fence. The Berry throughout has the characteristics of both its parents. Its period of ripening is after the raspberries are over and before the blackberries are ripe. It is delicious stewed, and makes a splendid jam.

Prices : Strong Plants, 7/6 each ; 84/- per dozen.

LAXTON BROTHERS . BEDFORD

A WARNING

SOUND healthy fruit does not grow upon Scabby trees. To ensure a productive crop next season remove all moss, lichen and loose bark, the breeding places of all insect pests.

Spray your orchard NOW with Cooper's WINTER SPRAY FLUID. It effectively kills moss and lichen, removes loose bark, thoroughly cleanses and reinvigorates the trees.

Non-Poisonous. *Does Not Burn.*

Ryders

Wonderful Wind-flowers.

Harbinger of Spring Anemones.

Ryders have pleasure in introducing to the gardening public the most wonderful group of Anemones that exists. A coloured plate in the catalogue gives some idea of their glorious beauty. They are hybrids of the grand old scarlet Wind-flower. All the cardinal colours and innumerable art shades are represented. They are in bloom long before any other Anemones, flowering as they do from February, when there are scarcely any flowers in our gardens, to the end of May. They are as hardy as anything known, succeed everywhere and bloom most abundantly; are delightful as cut flowers. They should be grown in every garden.

Price per dozen, 2/6; 50, 9/6; 100, 18/- carriage paid.

RYDERS BULB CATALOGUE which contains a coloured plate of these wonderful Wind-flowers in addition to numerous other coloured and black and white illustrations sent post free on request.

CLEAN CROPS ARE GOOD CROPS

Health calls for cleanliness

INSECT and fungoid pests attack plants and trees—poor crops naturally follow.

Before full yields can be obtained, real plant health is necessary. *This calls for quite unusual cleanliness.* Only a thorough system of plant hygiene cleanses trees and plants, controls the pests, and makes good gardening possible.

BEGIN now to safeguard crops. Chemically sound cleansing agents that have been proved successful by trade growers are now available for every garden. For your own plants' sake adopt this quite unusual cleanliness

awards of merit and first-class certificates were awarded him. Although few peas are now issued under the name of Laxton, this does not mean that this pioneer firm has given up the raising of new garden peas. They prefer, however, to sell the crop outright, and they only supply peas to the wholesale market. When we visited the nursery we saw a most interesting range of experiments in a four-podded pea, which certainly looks promising enough for the future. It is to be hoped that in a very few years they will succeed in fixing the strain, which should make a valuable addition to our best croppers.

Raising Strawberries.

Among amateurs the name of Laxton is most closely associated with the raising of strawberries, for which this firm is supreme. When one knows that Royal Sovereign is a product of this firm, there is little more that can be said about them as strawberry raisers. On our visit, luckily in the strawberry time, we had a chance to examine the care with which selection in strawberries is carried out. Row upon row of seedlings were ticketed and starred and double starred and treble starred. Every point for and against is carefully examined and docketed. The result is most interesting and proves that strawberry tasting is a science, like tea tasting. Every conceivable variety of strawberry was being tested, and it was interesting to note that not one out of a whole row of American bred strawberries could hold a candle to even the most mediocre of English varieties. Even the tyro could distinguish by tasting the worth of Messrs. Laxton's new strawberry, The Duke, which is, in fact, an improved Royal Sovereign. The flesh was particularly firm and the flavour delicious. The trials are narrowed down to such an extent that many seedlings which a novice would unhesitatingly class as a first-rate berry were marked for discarding.

The nursery covers so many acres that it was impossible to see it all in one afternoon, but we were much interested in the long ranges of new crosses in apples, pears and plums, particularly in the series with Cox's Orange Pippin as one parent. This series should produce some admirable varieties in the future. All the trees appeared to be fine growers and many of them carried an excellent crop of apples, most of which showed their strong relationship to Cox's Orange. Bedford has a hard climate and no gardener in any part of the British Isles can doubt of the substance of the fruit trees sent out by this firm. Another most interesting feature was the row upon row of various types of raspberries and hybrids between the raspberry and the bramble, such as the comparatively new Veitchberry, that combines all the flavour of both parents. We were shown how difficult is the work of crossing these two fruits owing to the high percentage of unfertile progeny that ensues as the result of crossing. In every branch of fruit culture this nursery shows to what a fine art this most interesting branch of gardening has risen. Acre upon acre was to be seen of bushes, standards, half-standards, fan-trained, cordons, all in the most excellent condition and worthy of all that is best in fruit culture.

Lately, Laxton Brothers have produced many fine new roses, among them the famous Bedford Crimson, that was awarded the Clay Cup in 1924 for sweet scent. It is a magnificent crimson rose, that in addition to its other merits, does not fade, for at the time of our visit we saw an acre of it in full sun, whether in bud or full bloom, not a bloom showed a sign of that blue tinge that is such a drawback to so many crimsons. Another worthy rose was a new single polyantha called Laxton's Pink Delight, most free flowering and of a charming shade of pink.

ONE OF MESSRS. LAXTON'S FINE EXHIBITS OF STRAWBERRIES.

OUR SERVICE BUREAU

Though so many subjects are dealt with in each issue of THE GARDEN, *it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, there is always information available from a staff of expert contributors and consultants; and there is no charge for this. It is one of the additional means of service which* THE GARDEN *is glad to render to its readers.*

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope and the coupon, that will always be found in each issue, shall be sent with the enquiry. We would point out, however, that we cannot undertake to supply readers with plans and designs of gardens, but will willing assist in giving suggestions for planting.

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2.*

We have selected the following enquiries, with their answers, as being of more general interest, and therefore worthy of publication

A Flowering Shrub for the Front Garden.

I require a flowering shrub for my front garden, which faces due west and measures about 12ft. by 4ft. There will be nothing else in the garden, and I should want a fairly bushy plant which would not exceed 5ft. in height when fully grown. What would you suggest?—T. W. J., Leicester.

We suggest that in your front garden you plant either a philadelphus, such as P. Virginale or P. Voie Lactee, or a deutzia. Both are much the same in general habit and flower decoration. They make bushy plants and are quite effective in May and June. In addition, they are easily kept and little pruning is required. The only thing is that all dead wood should be removed before the winter months.

Shrubs and Flowers for an Old-Fashioned Garden.

I have a fairly big garden, both front and rear and also side, which I am turning mainly into lawn. There will be a rose garden and a long perennial border, but I wish to put down a good few flowering shrubs and evergreens. Could you give me any advice as to what shrub would go best with a Tudor house—some of the old-fashioned kind, to give the right effect? I wish the garden to fit in with the house.—M. M., Belfast.

The following list of shrubs would be suitable: Daphne Mezereum; andromeda; Berberis Darwinii; box, euonymus, honeysuckle, lilac, magnolia, philadelphus, prunus, pyrus in variety, ribes, azaleas, spiræa, almond, holly, laurustinus, weigelia, aucuba, buddleia, hydrangea, fuchsias, veronica, escallonia and rhododendrons if the soil is free from lime.

You should include in your list of plants for the herbaceous border, lavender, St. John's wort, deutzias, spiræas, Anemone alba and A. japonica, sunflowers, columbine, saxifraga, campanulas, foxgloves, Solomon's seal, iris, dielytra, delphiniums and pyrethrums. They would tend to give an old-world appearance to your garden.

Remedies for Pear Scab.

I would be much obliged if you could tell me what is wrong with my pear tree. It crops very well, but the fruit always splits, so that most of the pears are useless, as they will not ripen. The soil here is a very poor granite gravelly one—I fear not at all suitable for fruit trees. I would be very grateful if you could tell me anything I could do to improve the fruit.—K. S., Dumfries.

The pears you send are attacked by the pear scab disease, which causes the skin to

Digitized by Google

crack and harden when the scabs are formed. It is a prevalent complaint in many gardens. It may be remedied, however, by spraying in springtime with Bordeaux mixture. Spray once just before the petals open in spring and a second time a few days after the petals have all fallen. This will keep the fruit clean, if the spraying is thorough and a good brand of Bordeaux mixture is used. The disease is carried over from year to year in the wood of the tree, however, and at the winter pruning all diseased shoots should be cut clean away. If the tree crops well in most years there can be nothing wrong with the soil, and probably all the assistance the tree needs is a good mulch of farm or stable manure laid over the roots in February or March each year.

Quick-Growing Hedge Plants.

Will you tell me which would be the best to purchase, to make a thorny, impenetrable hedge—quickthorn, or Myrobella plum? As it is for a new house, I want something that will grow quickly. Can you tell me which would be the quickest growing and most suitable for an ornamental hedge upon a bank surrounding a crazy-paved garden, also for a background to a herbaceous border 150ft. in length and 12ft. wide—Thuya Lobbii, Lonicera nitida or Cupressus macrocarpa? We shall not be in occupation until March. Will that be too late for planting, or what time would you recommend.—E. A. H., Basingstoke.

We should suggest that you plant quickthorn to make a thoroughly impenetrable hedge. It grows fairly rapidly and, in addition, gives quite an attractive effect to the garden.

In the other position, we suggest that you plant Cupressus macrocarpa, about 18ins. to 2ft. apart. It makes an exceedingly graceful hedge, and is a very rapid grower, and also does well in the majority of situations. You could either plant Cupressus macrocarpa now, or wait until April next year.

Evergreen Flowering Shrubs for Poor Soils.

Will you be kind enough to give me the names of four or five evergreen *flowering shrubs, of fairly uniform shape and not too expensive? The border in which I propose to plant same is in a sunny position, but the soil is light, very poor quality, and with ballast subsoil.—H. W. F., Grays, Essex.*

The following are the names of six good evergreen flowering shrubs, inexpensive and of average height: Berberis Darwinii, B. stenophylla, Escallonia langleyensis, Choisya ternata (this should not be planted in too exposed a situation, it does particularly well against a wall), Osmanthus Delavayi (quite a charming small shrub, with most sweetly scented white flowers), Olearia Haastii and Carpentaria californica.

Climbers for Pillars and Arches.

I have a raised terrace path having eight larch poles placed about 4ft. apart to form a screen. The poles have simple cross members connecting them, with angle struts, and the recess for the seat will be roofed over with lighter poles in the form of a pergola. I shall be glad if you will kindly advise me as to the choice of suitable climbers to clothe the screen and cover the top of the pergola, giving the full name of the varieties suggested. I should like at least three climbing roses, and these I should suggest placing on poles Nos. 3, 4 and 5 to form a good "roof" over the seat, and where their branches will not impede progress along the path. My own scheme is: 3, American Pillar; 4, Alberic Barbier; 5, Tea Rambler—all old favourites of mine. The other five poles which have had to be placed close to the path seem to call for "non-thorny" subjects, such as honeysuckles, clematis, etc., and I should like to see Clematis Jackmannii on pole No. 6, and a paler mauve one on pole No. 2 (? name of a good variety). If it is thought that these clematis would be insufficient to clothe the poles properly, what else could be planted in addition? And what could I use on poles Nos. 1, 7 and 8? I saw Vitis vinifera purpurea at Waterers', and it seems a nice thing for the purpose. Kindly let me have your criticism and advice. Note: the soil is ordinary heavy loam on yellow clay, and the screen gets plenty of sun except in the winter months, when it is shaded by the house. In another part of the garden I have an arch built on the same lines as the screen. The side supports of the arch are 2ft. wide, so I think I could use two plants to each side. My suggestion is one rose on each side—say, Shower of Gold and Hiawatha—and two more clematises, but I hardly know whether this would be harmonious. Another idea was to use Polygonum baldschuanicum on one side, with another plant that would afford a good colour scheme if the flowering period was the same.—F. O., Hendon.

The varieties of roses you name are quite good ones for the purpose. Of other climbers plant Clematis Jackmannii on pole No. 6, certainly; C. Marcel Moser on pole No. 2; C. paniculata on pole No. 8; Jasmine officinale on pole No. 1; and Honeysuckle fragrantissima on pole No. 7. It would be advisable to plant Vitis vinifera purpurea and Solanum jasminoides for training over the garden seat or arbour, also. The two roses you name will do nicely for the arch, or the polygonum or Ceanothus dentatus.

Fragrant Roses for Trellises.

Will you please advise me as to the choice of two roses to cover trellis fixed on back wall of house to a height of 9ft. or 10ft.? Wall faces south-east. I want fragrant roses, with as long as possible period of blooming. One should be yellow, as Gloire de Dijon, Maréchal Niel or Mme. Jules Gravereaux. Would any of these be suitable? The other red—Paul's Scarlet. Is this fragrant, and would it do on the wall? Or perhaps you can tell me some thing more suitable.—F. N. N., Kingsbury.

The two varieties we recommend for the trellis are Gloire de Dijon and climbing Château de Clos Vougeot or, if the colour of the latter is considered too dark, try Grüss an Teplitz. Paul's Scarlet Climber is not a fragrant rose, nor is Mme. Jules Gravereaux so fragrant as the other varieties mentioned.

Shrubs for Autumn Colour.

In my border, facing south-west, I have Berberis Thunbergii, Cornus alba and, nearer the front, Berberis Wilsonæ. In the opposite border, facing north-east, Berberis Aquifolium and Leycesteria formosa are growing.

Will you please quote me another suitable variety for the former border, and two or three varieties for the latter? I require the shrubs primarily for autumnal effect, in foliage or berries, and to average about 4ft. or 5ft. in height. The situation is fairly open, but my subsoil is clayey.

I found your article on "Autumn Tints" in a recent issue very interesting, but am in doubt as to which to plant, as I am ignorant of the average height reached by the different varieties. Presumably these shrubs can be planted any time from October to the end of March, given suitable weather.

Will you also please state whether Acer Negundo and Prunus Pissardii are difficult to grow?—D. F. T., South Tottenham.

We should suggest that you might include one or two additional berberis, namely, B. Darwinii, which makes a shapely bush and can be kept to a height of 4ft. to 5ft., or B. yunnanense. Viburnum Opulus, either the common one which is native to this country, carrying bright red berries, or the variety fructu-luteo, with yellow-orange berries, would be suitable. Both of these grow to a height of 5ft. Then comes Euonymus latifolius and europæus. Cornus sanguinea makes a most brilliant show in autumn, especially if given a moist position, and, since your subsoil is of a clayey nature, this should do well.

Prunus Pissardii and Acer Negundo are not difficult plants to grow. Acer Negundo should not be given too exposed a position. Prunus Pissardii will thrive fairly well in any position. It looks best more or less as a background to smaller plants. It generally reaches a height of about 12ft. These evergreen shrubs which have been mentioned should be planted forthwith. The deciduous kinds are best planted any time during the present month when the weather is open.

Plants for Concrete Walls.

Near Sevenoaks I have a concrete cottage (hard cement outside), and wish to beautify it by plants which will not eat into or cling to the cement, and cause cracks. The walls are due north, south, east and west. Nails may not be driven into the walls.

Would you be kind enough to suggest the most suitable plants which will grow to a height of 10ft. or more, and mention upon which wall they should be?

I should like a pyracantha, if suitable, and should be glad to know where I can procure one with red (*not orange*), *almost crimson berries.—C. R., Bromley, Kent.*

We should suggest a few of the following shrubs would be suitable to plant for wall decoration round your cottage: Pyracantha coccinea Lalandei (bright crimson berries), Cotoneaster horizontalis or Simonsii, Escallonia langleyensis (for south or west wall), Choisya ternata (for south or west wall), Tamarisk (for south or west wall), Ceanothus rigidus or thyrsiflorus, and Cydonia japonica (for north wall).

If any of the walls of your cottage are particularly expansive, then we should suggest that you grow a large growing plant, such as Wistaria chinensis or Magnolia grandiflora, but only plant these where there is sufficient space for their expansion.

Trees for a Narrow Garden.

I have a narrow garden, 21ft. wide, with fruit trees along one side. For about 30ft. along the other side I desire to plant a few trees to meet the following requirements:

(1) To screen the garden somewhat. One to be 12ft. to 15ft. high when fully grown and evergreen. The others 10ft. to 12ft. high and either evergreen or deciduous. (2) Trees that will branch out more like fan-shaped fruit trees, so as not to overhang the garden. (3) Ornamental, i.e., with flowers or berries, etc. (4) With branches starting, say, 4ft. from the ground so that I may plant flowers in the border between them.

I do not know whether these requirements are impossible of fulfilment, but if you could give me any assistance I shall be grateful. If trained fruit trees would do for some, that would suit me. I should perhaps add that the soil is heavy clay and the situation ten miles north-west of London.—T. W. T.

The best tree for your purpose is Prunus Pissardii, which grows to an average height of 12ft. to 15ft. It is quite attractive in flower and fruit, and is a good colour both in spring and in autumn. It does not branch until it reaches a height of 3ft. to 4ft., and would be a suitable subject for under-planting with more dwarf-growing plants. It also makes quite an effective screen. Robinia Kelseyi, a charming small spring-flowering tree, with rose-pink pea-shaped blossom, would also be suitable for your purpose.

Small Orchards

No matter how small or large the orchard, it pays to use Stictite Tree Banding Compound.

Winter Moth rises from the soil early in October or late September, and the females (being wingless), at once crawl up the tree trunks in order to deposit their eggs in the branches.

By banding the trees with Stictite in the autumn you can prevent the eggs being laid, and so avoid having to spray for the caterpillars in the spring.

1 lb. of Stictite will do 9 to 12 trees of about 8 in. diameter.

½-lb. 1/6 (post 6d.); 1-lb. 2/9 (post 6d.); 2-lb. 5/- (post 9d.); 4-lb. 10/- (post 9d.); 7-lb. 17/6 (post 1/-).

Greaseproof Paper, 5 ins. wide: 6 yds., 2d.; 12 yds., 3d.; 25 yds., 6d.; 50 yds., 9d.; 100 yds., 1/6; 200 yds., 2/6.

Write for Descriptive Folder.

Stictite is sold by Nurserymen, Seedsmen, Florists, Ironmongers, Chemists & Stores. If any difficulty, please write to Abol Limited, 9, Beltring, Paddock Wood, Kent.

SOME COOKING APPLES WORTH PLANTING

This is a list of good cooking varieties which amateurs may find useful when making a selection for planting next month.

Early Victoria (*Emneth Early*).—This codlin apple is one of the best early cookers. It is of rather irregular shape, but tapers up towards the eye, which is small. The growth is rather weak, but it is a heavy cropper. Last year we saved a lot of small fruits; they were too small to sell as cookers—and kept them until November, when they had assumed a good golden tinge, and found a ready local sale for eating—not exactly good-flavoured, but they were sweet, and when small boys are the customers, quantity and sweetness come before flavour.

Ecklinville Seedling.—In my opinion the best early cooker. Although usually classed as later than Early Victoria, the fruits swell early, and usable fruits may be picked in late July. Rather flattish in shape, with a broad base, it takes on a slight flush in late summer. The growth is fairly strong, but, unfortunately, it is liable to canker. It is our most regular cropper.

Stirling Castle.—A cooking apple which is largely grown on account of its heavy cropping powers. If grown on Paradise stock (we have some on Malling Type II), it is liable to fruit so heavily that very little growth is made. A medium-sized fruit, round in shape, it is in season until October or early November. It is a weak grower, and I should prefer to have it on a strong growing stock.

Lord Derby is not such a regular cropper as Stirling, but is a good cooker and must be classed as one of the twelve best. It is a strong grower, producing large oblong dark green fruits.

Lane's Prince Albert.—Useful, as it keeps till Christmas and even later. Makes a very sprawling tree, but is not a strong grower. A heavy cropper (we have picked a good crop from it this year), it is a conical fruit, medium to large in size, and with a bright flush on the sunny side. If only one cooker is to be grown, I think this would be the most useful.

Warner's King.—A distinct and useful cooking apple which will keep until February. A strong grower which is sometimes attacked by canker, it is popular on account of its size and cooking qualities. The fruit has a very broad base with russet stripes radiating from the stalk cavity.

Bismarck.—Quite a moderate grower, but a grand cooker. Distinctly conical in shape, this apple is a good red colour on the exposed side. The growth is rather spreading, and it is one of the heaviest croppers, keeping till February. This variety is rather subject to scab.

Newton Wonder.—The peculiarity of this strong-growing, free-cropping variety is that a large percentage of the large-eyed roundish fruits have a lump at the base of the fruit from which the stalk emerges. It will keep quite late in the New Year, is very heavy, and changes to a yellowish colour at Christmas-time. Often the whole of the apple is covered with a deep red flush. This apple is sometimes quoted as being suitable for dessert in March, but I have not found the flavour good enough for dessert purposes.

Bramley's Seedling.—The last and latest, but by no means the least of the cookers. This variety has, commercially, been planted more extensively than any cooking apple during recent years. A first-class cooker of irregular shape, it is a good cropper, a strong grower, and comparatively disease-free. Please do not confuse this apple with Crimson Bramley, which is not such a good cropper.

N. D. H.

How to Treat Garden Refuse.

IN both town and suburban gardens the question of suitably disposing of refuse—that resulting from decayed vegetable matter, weeds and other material of a like nature—is a difficult one in many instances. Where fires—garden smother fires—are allowed it simplifies matters considerably. I only know of two satisfactory methods of getting rid of garden refuse in an economic way, namely, by burning and burying in the soil. Hard matter, such as prunings, may be burned and the resultant ashes used in the borders; it is the only way, as hard wood, and even green twigs, should not be dug into the soil. Weeds and other succulent refuse may be buried, but not in the ordinary way. I prefer to treat all such refuse before burying it in the garden borders. The following plan can be carried out with good results. When the ground is being cleared of the accumulated rubbish the woody portion should be collected and kept by itself for that time, then be converted into ashes at the first opportunity. Keep the wood ashes dry by storing them, when cold, in bags or boxes in a cool, dry shed. They are excellent for tomatoes and generally, but especially for mixing with composts for seedlings in boxes and for seed-beds in the spring. The soft or succulent refuse, such as weeds and cabbage leaves, tree and shrub leaves, should be placed in a heap and salt sprinkled freely on each layer. Allow the heap to remain undisturbed for one month, then turn the rubbish, adding more salt. Three turnings should be the maximum when the prepared rubbish will be fit to dig into the ground as a manure for vegetable crops.

BOOK REVIEW.

Many of our readers will be pleased to learn of the re-issue of two of Miss Gertrude Jekyll's gardening works, namely, "Wood and Garden" and "House and Garden," by Messrs. Longman's, Green, at the price of 10s. 6d. net each. These volumes first appeared in 1899 and 1900 respectively, and were among the first gardening books in what might be termed the Revivalist period of gardening which led to the overthrow of Victorian ideas of stiff and formal gardening and the establishment of gardening as a pastime for the many and not, as was formerly the case, a pleasure of a few. Miss Jekyll, already well known to all readers of THE GARDEN by her simple articles on various aspects of gardening which appear in these pages from time to time, is one of our greatest amateur gardeners, and by her past efforts, enthusiasm and love of gardening, has done more to popularise the simple type of gardening than probably anyone, with the exception of Mr. William Robinson. Her books on gardening are all written in a clear, simple and homely way, and yet contain a perfect mine of practical information on the growing of flowers and their arrangement in the garden, together with suggestions as to planning and planting a garden, which all amateurs will find of the greatest assistance in their gardening problems. The secret of her success is that she writes as an amateur, with a fine appreciation and understanding of all the little difficulties that beset the amateur gardener. The popularity of the two present volumes is unquestionable, since their first appearance they have been revised and reprinted on several occasions. The present issues should prove every bit as helpful as those which have gone before; and with the ever increasing army of garden lovers there is a distinct need for two volumes such as these, dealing with the intimate aspects of gardening, and more especially since they are written by one who is an acknowledged expert on English gardens and gardening. Both volumes are profusely illustrated by clear and picturesque half-tone illustrations, many of which are helpful in themselves.

Chelsea Show 1928.

IN commemoration of the prospective inauguration of the New Hall in 1928, the Council of the Royal Horticultural Society has decided to offer a 100-guinea challenge cup for specialised groups, the subject of exhibition and allotted space of which will be varied from year to year.

The subject chosen for 1928 is "Stove and Greenhouse Plants," with a group space of 300 square feet, and it is hoped that by giving this early notice, amateur and trade exhibitors will make a special effort to stage comprehensive groups and the cultivation of these ornamental and interesting plants will be generally encouraged.

The prizes offered will be First Prize, 100-guinea Challenge Cup and £30; Second Prize, Large Silver Cup and £20; and Third Prize, Small Silver Cup and £10.

TRADE NOTE.

READERS will recall our drawing attention some time ago to spade boot cleaners which were put on the market by Mr. C. Van Der Byl. Owing to the popularity of these and at the request of many customers Mr. Byl has now adapted the specially shaped scraper blade for motor cars. It is fitted with two steel brackets so that it can be screwed on under the running-board of motor cars. This device will enable the motorist to free his boots or shoes of every particle of mud before entering the car. The scraper can be fitted by any garage at a cost of 4s. 6d. inclusive, and it should prove a boon to all sportsmen, farmers and keen horticulturists who are frequently visiting gardens and nurseries.

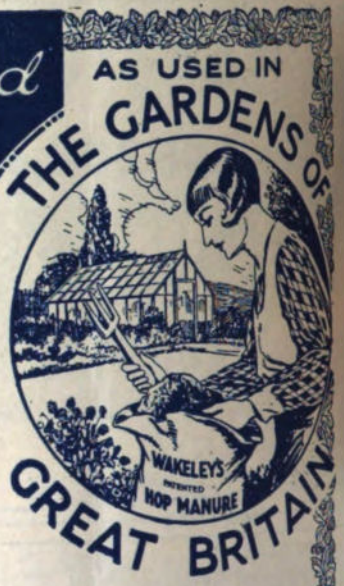
WAKELEY'S *Celebrated* Hop Manure

(PATENTED)

THE ORIGINAL AND ONLY RELIABLE SUBSTITUTE FOR STABLE MANURE



DIPLOMA AND MEDAL, ROYAL INTERNATIONAL HORTICULTURAL EXHIBITION, 1912.

DO YOU REALISE IT?

A large bag of WAKELEY'S PATENTED HOP MANURE at a cost of only 7/- carriage paid to your door (if within 25 miles radius of London, or at a trifling extra if beyond), GOES AS FAR AS A CART-LOAD OF STABLE MANURE, without any of the defects of the latter; gives better results, is easy and clean to use.
Every ounce of Wakeley's Hop Manure is of value to the soil, supplying the necessary HUMUS in addition to the valuable plant food. Worthless rubbish is not added to make weight (as is the case of some artificial manures advertised).
Thousands do realise it, the proof of this is the constant flow of UNSOLICITED LETTERS received from time to time in praise of the wonderful results obtained at such a moderate cost (see Catalogue for selection).

BEWARE OF IMITATIONS.—Genuine only in our Marked Bags, containing Guaranteed Analysis.

A BEAUTIFUL FREE CATALOGUE.—Giving full particulars and testimonials sent on receipt of post card.

CASH PRICES (including bags): Small (about 1 bushel), **3/-**; large (about 4 bushels), **7/-**; 5 large, **33/9**; 10 large, **65/-**; 20 large, **120/-**.

NEW HARDY CRIMSON BROOM

AT Chelsea Show (1925) the King said, "That red Broom is certainly very striking." This was the new crimson Broom "Dorothy Walpole," which received the unanimous Award of Merit from the R.H.S. as well as other distinctions in London and on the Continent. Plants have been sent to U.S.A., Canada, Australia, New Zealand, France, Holland, etc.

In the Field, *a well known ex-Curator of Kew Gardens wrote: "The richest coloured Broom known is one named 'Dorothy Walpole.' It is as hardy as the common Broom . . . and is very free-flowering . . . the colour is rich velvety crimson . . . more attractive than any of the coloured Brooms yet seen." The colour far surpasses Cytisus Dallimoreí, and the growth is as vigorous as C. Andreanus; it requires no special treatment nor any kind of protection whatever—just a hardy shrub for ordinary garden soil in any part of the British Isles, however far north.*

A Vice-Chairman, Floral Committee, R.H.S., wrote: "Everyone who has seen my plant has been astonished at its warm glowing red"; and from a lady in Devon: "I am so delighted with the Broom 'Dorothy Walpole.' It has done splendidly and is like a sparkling gem in the garden—one mass of flower."

NEW SEASON'S PRICES.

Strong pot-grown plants now ready for planting out, to flower in May, 7/6 each. Carriage paid rates to any station in Great Britain or Ireland: One plant, carriage paid, 10/-; two plants, carriage paid, 18/6; three plants, carriage paid, 26/-; six plants, carriage paid, 49/6; twelve plants, carriage paid, 99/-.

Coloured illustration sent on application if THE GARDEN *is mentioned.*

Wm. Watson & Sons, Limited, Nurseries, Killiney, Co. Dublin.

Notes from Maidstone.

MYROBALANS and MIRABELLES.

These two plums are often confused. The Myrobalan (Prunus cerasifera) when first introduced into Europe was thought to be the source of the dried fruits known as Myrobalans, so largely imported into Europe in the Middle Ages for medicinal uses, hence the name was applied quite wrongly to the plum. There is no better fruit for bottling, and we offer the Red and Yellow varieties, extra stout Standards, at 7/6 each.

The Mirabelle is a miniature gage of delicious flavour and making an unequalled preserve, Half Standards at 7/6 each.

THE GARDEN

Vol. XC.—No. 2866. NOVEMBER 6, 1926. Price Twopence.

THE IMPERIAL FRUIT SHOW

THIS Show, which opened last Friday at Holland Park Hall and remains open until November 6th, comes at a most opportune time, when public interest is centred on Imperial affairs, with the meeting of the Empire Conference. Every year, since its inauguration as an annual event, it has shown increasing vigour and vitality and the general display at Holland Park on the present occasion equals, if it does not surpass all the previous exhibitions. All interested in fruit production and the subsidiary branches of the industry, should not fail to pay a visit.

That the way to strength lies in co-operation is fully exemplified by the many and divers trade exhibits which are staged at the Show. All branches of the industry are represented and it is difficult to determine which, if any, is the most important. Each is necessary for the production of first grade fruit such as is displayed. This year, the largest group display is under the wing of the Empire Marketing Board, in which are to be found all our Dominion exhibits. This exhibit forms a part of a larger scheme to popularise our Dominion products and in this case particularly to encourage the home market to rally in support of British and Empire-grown fruit. This exhibit undoubtedly shows the many sources of supply and the wealth of fruit production in the different parts of our Empire. South Africa stages one of the most attractive exhibits at the Show in the display of oranges, grape fruits, pine-apples and dried fruits. The citrus industry in the Cape becomes of more importance every year, as their table of exports testifies. Last year the exports in fresh fruit totalled over two and a half million boxes. Now the Dominion is taking up pineapples for canning purposes and a flourishing subsidiary industry seems assured, as the products are good. Canada supplies a magnificent apple exhibit, grown and supplied by three of the leading provinces, Ontario, British Columbia and Nova Scotia. The apples shown in three or four commercial varieties, are staged in standard boxes packed for market, or in fancy baskets. A rather novel exhibit comes from Australia in a display of currants, raisins and sultanas in baskets. Various brands of canned fruit are also shown. From Jamaica comes a representative collection of fruit products in bananas and grape fruits, while the latter also appear from the Gold Coast with oranges, pineapples, and other citrus fruits. The fruit industry in the Gold Coast is a comparatively new one and with increased facilities for marketing and transport is assured of building up a successful future. This comprehensive exhibit also includes a wide range of British canned fruits, arranged under the auspices of the National Food Canning Council, which is engaged in arousing public interest in the work of the various British canning firms. This is a most interesting exhibit from more than one point of view. It will do much to stimulate the growing of various kinds of fruits in this country, in that it creates a ready market for such fruits as strawberries, raspberries, loganberries, plums, damsons, etc., and in addition it offers to the public British grown fruit in practically natural form, available over the whole year. It is undoubtedly a branch which will do much to increase and popularise fruit growing in these islands once the products become more widespread.

There are many interesting and attractive trade exhibits from our leading wholesale firms in this country engaged in the marketing of fruit products, while allied branches are represented by the sundry exhibits of insecticides and fungicides, by such firms as Messrs. McDougalls. The amateur gardener should pay particular attention to these displays, since every year the careful tending of the fruit crop, however small, becomes of increasing necessity and the improved methods of spraying with up-to-date materials should be noted for future use. The sections devoted to competitive fruit classes are always of considerable interest and once again these serve to show the supremacy of home-grown produce. Even in such a bad apple year as we have experienced, the exhibits of this fruit are almost up to standard. The fruit packed in standard boxes or barrels is in fine condition and the colour, size and grading leave nothing to be desired in the marketing of produce. These exhibits from the various counties of England certainly show that the home country can produce good fruit and that those engaged in its production and distribution are alive to the need of marketing it in a suitable way.

The scientific exhibits, illustrating the research work which is being carried on at East Malling, Long Ashton and Campden Fruit Research Stations, forms an important feature of the Show, which all interested in fruit should notice. All the various problems connected with fruit culture and the preservation of fruit are dealt with, while attention is also directed to the many diseases met with and the necessary remedial measures to be undertaken so that healthy fruit crops may be made possible.

HAVE YOU

¶ *Made preparations for protecting your frames and tender plants during frosty weather?*

¶ *Taken into a cold greenhouse or frostproof shed your tub plants, such as hydrangeas, bay or agapanthus (African lily), which have stood out of doors during the summer?*

¶ *Protected from cold and wet by covering with pieces of glass your tender, hairy-leaved rock plants?*

¶ *Dressed with ground lime at the rate of 40z. per sq. yd. any mossy portions of your lawn?*

¶ *Pruned, cleaned and top-dressed your peach trees?*

¶ *Protected your autumn cauliflowers by snapping and bending over the surrounding leaves?*

¶ *Examined your potato store, removing all potatoes showing signs of decay?*

RESULT OF CLIMBING ROSE COMPETITION.

OUR Climbing Rose Competition has been very popular with our readers. The result of the vote is as follows:

1.—Dorothy Perkins.

2.—American Pillar.

3.—Alberic Barbier.

4.—Paul's Scarlet Climber.

5.—Excelsa.

6.—Hiawatha.

Remarkably few votes separated the first two, while the fourth and fifth were also close. No reader gave the list in proper order, but two gave the correct roses. The first prize is awarded to Miss E. V. Bray, 44, Fordington Road, Highgate, London, N.6; the second to Mr. W. T. Little, 16, Ludlow Street, Penarth, Glam. The third prize is awarded to Mr. D. L. Don, 53, Church Street, Caversham, Berks, who was next in order of merit.

The illustration in colour on the front cover has been supplied by Messrs. Sutton and Sons, of Reading, and shows some of the modern varieties of annual asters raised by this firm.

For this month's Competition see page 641

PLANTS AT THEIR BEST IN AUTUMN

Gardeners are always glad to receive information about plants that have been particularly noted in other gardens. Week by week plants that are really worth growing are described in this page.

Chrysanthemum Horace Martin.

ALTHOUGH the trade catalogues usually quote August and September as the flowering period of this chrysanthemum, I have contrived to keep a good supply of it going from the early days of September until the time of writing these notes, and even yet (the last week in October), several plants are well burdened with excellent flowers. It seems to me that chrysanthemums in October are a greater treasure than in August, and although, admittedly, we have had an exceptionally good autumn, it is worth while even to risk a possible collapse of a few plants for what may certainly be considered an even chance of securing a fine late show.

The method by which my late display was secured is perfectly simple. Cuttings were taken as soon as the old stools provided them, and in May some of the plants were transferred to a border with a south-western aspect, and others were placed near the wall of the house, facing north-west, and sheltered from east winds by a projecting porch. When the plants had made some growth in their new quarters—by mid-June—they were, with the exception of two in each batch, cut back to less than 6ins. from the ground, and thus made to produce entirely new branches.

The four mentioned were simply pinched at the points of the shoots and, of course, broke quickly. These plants gave me the first supply of bloom, and the south-west border came in to maintain a supply throughout September, those on the cooler house-border, which received only afternoon and evening sunshine, brought up the rear for an October show.

There is a distinct advantage in the choice of aspect for this batch, for during the latter half of October, when frosts occurred, the plants were screened from morning sunshine and by syringing early in the morning with cold water, a gradual thaw was ensured on two or three occasions, leaving the flowers undamaged by frost.

Horace Martin is not a new variety, but it is one of the best of yellow chrysanthemums for outdoor culture.

Violet Lloyd George.

THIS violet, under frame culture, is a flower of no particular season, but it is to be appreciated very highly for the steady persistency with which it will yield its fine blossoms during the departing autumn and advancing winter. It is not a matter of affording it heat, for in common with the rest of its family, it resents artificial warmth; the secret of heavy cropping lies in building up strong, robust plants.

The majority of failures with frame violets are due, in the first place, to late propagation, and in the second place, to covering with glass plants which have not been long enough in the frame beds to be well enough rooted to respond to the inducement to put forth flowers. The production of really good winter-flowering plants is a two-season's job. The propagation should be taken in hand during April or May, and if the young plants can be transplanted to the frames the following autumn, the lights should only be used for the purpose of sheltering them from inclement weather, and should be removed on all favourable occasions, always allowing ventilation when covering is necessary. The summer following should be devoted to feeding and strengthening the plants in readiness for a good cropping season the ensuing winter.

Of all varieties Lloyd George produces the finest and most substantial flowers, the centre being strikingly attractive. It is also a most obliging variety in the readiness with which it responds to judicious coaxing into bloom at this period of the year.

The "Chinese Lantern."

NOW that the foliage has fallen, the bright flame red of the larger of the two popular kinds of the "Chinese Lantern" (Physalis Franchetti) provides a splash of very attractive colour. Where there is a fairly large mass it is worth while leaving some stems to blaze away as long as they will, and it will be some time yet before they flicker out and leave the spot dull and colourless, but one can scarcely do this when only a few are grown, because they are so valuable for indoor decoration.

THE POPULAR "CHINESE LANTERN."
Admirable for indoor decoration.

It has rather surprised me to learn from various friends that they experience difficulty in growing Physalis Franchetti, but in some cases I have discovered that the long white roots have been planted perpendicularly in the ground. This is an error; the best plan is to open a trench 6ins. deep, level the bottom and lay the roots thinly along it. If the soil is inclined to be heavy, scatter some sharp grit among the roots, cover with soil and use any manure available as a mulch. It will do more good above than below the roots.

A Shrubby Veronica for the Rockery.

IN porous, sandy soil, made tolerably moist by incorporation of rough fibrous peat, Veronica salicornioides now wears the appearance of a particularly compact, bright golden conifer. It is very serviceable on the rockery, where something is required to vary the effect of prostrate alpines. It is a plant which seldom flowers, but that is of small account, its beauty and serviceability rest in its shrubby character and pleasing tints of yellow and bronzy green.

One cultural hint that may save disappointment in establishing purchased plants is, bury all bare stems by pegging down and packing gritty compost in between the growths right up to the fresh green growths. The buried stems will emit fine fibrous roots, and the whole clump will soon become a dense mass of beautiful fresh growth.

Dahlia Dazzle.

IT was a good name to give this miniature peony-flowered dahlia, for its colour is really dazzling when a gleam of October sunshine catches its gently waving flowers, which are borne in a crowd well above the foliage of a compact, bushy plant. Dazzle is vivid scarlet, the neat flowers having two rows of petals and a small golden disc. It came to me from Dickson and Robinson, Manchester, and is altogether a grand little flower.

A First-rate Garden Aster.

DESPITE the recently acquired wealth of beauty and variety which abounds in the modern Michaelmas daisies, we cannot afford to abandon so elegant and delightful a plant as Aster Tradescantii, for the simple reason that when practically all the rest have faded away, and become just so much fodder for the garden bonfire, this extremely graceful, pure white flower comes into its own, and provides material which demands no skill in arranging as cut flower decorations.

Aster Tradescantii should be lifted every spring, the growths being pulled carefully apart and planted singly, for it is thus that full development and blossoms of good size are secured.

A Fine British Fern.

CONNOISSEURS of British ferns will not be alarmed at the ponderous name of this real treasure, (Polystichum aculeatum pulcherrimum Bevis var.) for even in a family so rich in choice varieties as the polystichums there is none to outclass this pulcherrimum of Bevis.

Its graceful fronds are outlined with marvellous precision, and the tint of green, fresh and pleasing to the eye, is rendered the richer by a wonderful sheen as glistening as polished jade. The plant makes wonderful fronds, and at this season of the year, with growth completed and fronds undamaged by rough weather, it is more imposing and superb than many of the much esteemed exotics of the stove.

The Merryweather Damson.

Not yet has the full significance and value of this treasure among fruits been realised. The old types and varieties of damsons were trees to plant as wind screens around orchards, with the hope that some time fruit might appear; but it was certainly making poor use of garden space to plant trees of the ordinary damsons which generally delay fruiting until fifteen to twenty years of age, and seldom bear crops two years in succession.

The Merryweather is a marvel by comparison. I have seen a respectable show of fruit on a three year old "feathered" tree; I have seen the same trees crop heavily for four successive years, and in point of size the fruit bears more resemblance to the Orleans plum than to the common damson, but the distinctive flavour is well preserved. Plant the Merryweather Damson is sound advice.

A. J. MACSELF.

WHAT CAN BE DONE IN TOWN GARDENS

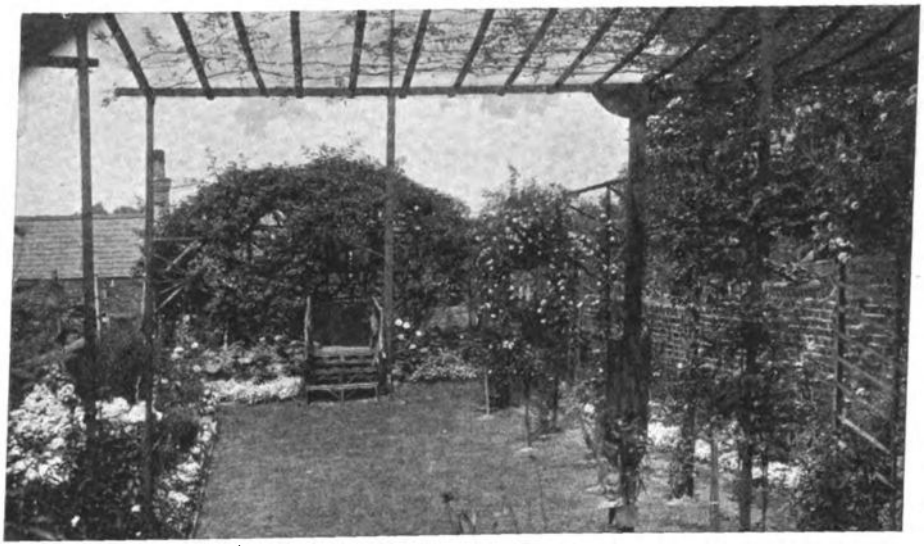
Many people imagine that plants will not grow in or near a large town, and for that reason design a garden containing more stone than plants. Such is not the case, however, as these three examples prove, taken as they are from different parts of London. All these are charming gardens with a wealth of bloom over the greater part of the year. If many amateurs who have hitherto been unsuccessful in their attempts will follow on the lines suggested here, the establishment of a pleasant little town garden will only be a matter of time.

STRICT town gardening is in a class by itself, but in many instances merges unconsciously into suburban gardening. To a certain extent, the difference between the two lies in the wider choice of plants which exists for the latter and not the former. Conditions in a town are generally different from those met with in the suburbs. There may be a lack of sunshine, which must of necessity govern the selection of plants and their arrangement and must, to a certain extent, influence the actual design. Still, the main object in every case should be to grow flowers and grass. A small well kept lawn is one of the greatest assets to any garden, and nowhere is it of more importance than in a town garden. Even although it may prove difficult to establish, persevere with it until the grass responds. Give the lawn the sunniest position there is, because it is an impossibility to produce a good lawn without sunshine. Arrange the garden on simple lines. The simpler it is, the more effective it will be. Many people advocate the placing of vases here and there in a town garden, but they are unnecessary in such a small space, and, moreover, lend that formal appearance which is cold and uninviting, a point to be avoided, especially in a small town garden.

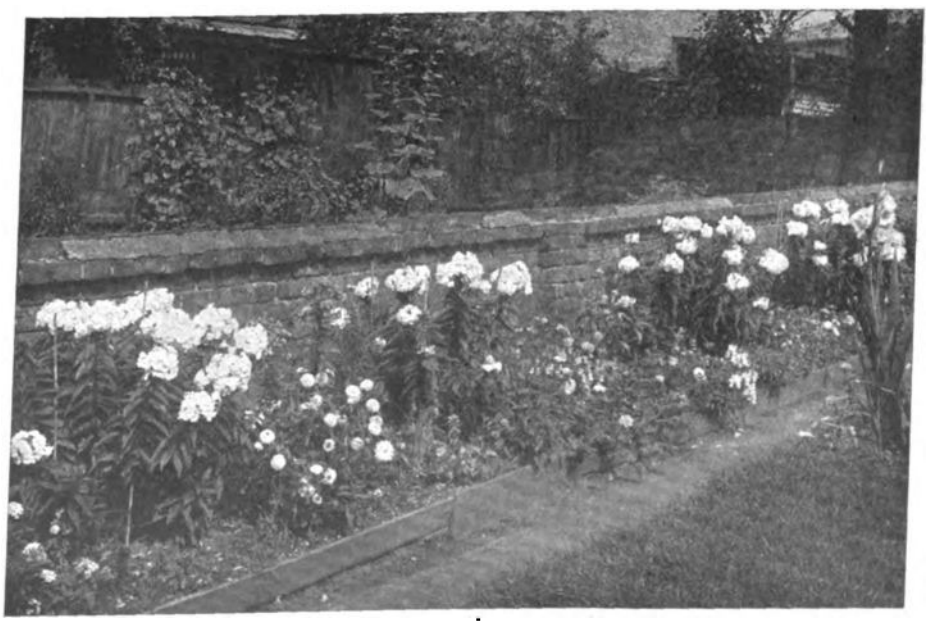
The first of these illustrations shows a pleasant garden in one of the suburban districts of London—in West Norwood, where residents are, on the whole, freer from the defects of the town than the majority. This garden has not the disadvantage of being closely surrounded with high walls of dull brick and mortar, or yet by the presence of houses immediately beside it. For that reason the owner has been allowed more freedom in his treatment of the ground and in the selection of his plants. The garden is of an average size, such as is owned by the majority of amateurs in the outlying districts of a large town. It is 100ft. long and 30ft. wide. The general arrangement is a most effective one, as can be seen from the illustration. The border plants are well grouped with regard to their height, and dwarf, compact growers, such as candytuft, blue lobelia and alyssum make up the edging, while in the rear ranks the taller-growing annuals and perennials complete an attractive scheme. Among the plants contained in the border are gladioli, phloxes of various colours, delphiniums, gaillardias, Canterbury bells, sweet williams, geums, antirrhinums, Michaelmas daisies, coreopsis (so excellent for all town gardens), chrysanthemums, scabious and roses of various kinds. The plants are all first-rate herbaceous subjects and respond well to cultivation in small spaces. They are all plants which the amateur need have no hesitation in including in any border planting scheme, and this autumn, when renovation work is being carried out and additions are being made to the border, plant a few of these, if they are not already represented, so that next year the colour display will be considerably enhanced.

The second illustration is of a small but well kept garden in south-east London, of some 70ft. long and 30ft. wide. Here, again,

A WELL ARRANGED HERBACEOUS BORDER IN A TOWN GARDEN.



A TOWN GARDEN IN WHICH ROSES PREDOMINATE.



PHLOXES RESPOND WELL TO TOWN CONDITIONS AND SHOULD BE IN EVERY TOWN GARDEN.

Digitized by Google

full use has been made of the space at the owner's disposal, and quite a host of good garden plants are housed within its limits. The owner shows a preference for roses, and on the pergola seen in the illustration many varieties of rambler roses are grown, including Hiawatha, Coronation, Blush Rambler and Albéric Barbier. In addition, many of the latest bedding varieties are grown, and such sorts as General McArthur, Ophelia, William Allen Richardson and Mme. Abel Chatenay do particularly well in this district. Quite a number of decorative herbaceous subjects have been planted to make up what is a most attractive garden.

The last garden illustrated is situated in North London, and not very far from the City. As can be seen, it is chiefly a town garden, being surrounded by houses or walls on its four sides. It is the standard type of a town garden, and receives a limited amount of sunshine owing to its walled-in position. For that reason the owner has been limited in his choice of plants and has restricted his selection in the main to phloxes, scabious and coreopsis.

The phlox responds excellently to the conditions met with here and every year magnificent heads of bloom are displayed over a period from July until September. Where any reader has a garden in a similar situation and desires a plant to give as much show and colour as possible, then the phlox is to be recommended. It does well in light soil and does not require much sunshine. In addition it is easily grown and easily propagated by cuttings or division, which makes it a plant to be valued by the keen amateur.

THE JOY OF MAKING A NEW GARDEN

BY GERTRUDE JEKYLL.

This article, with accompanying plan, suggests a design and method of planting up an area slightly larger than those previously dealt with.

THE ground on which this house stands is greater in extent than some that have lately been considered, and the house is higher in worth or rental. The gate of the path to the front door is close to that of the garage. Tradesmen enter by the garage gate and have an easy route to the kitchen door. The main house door faces nearly west and the principal window on that side looks out on to a good mass of flowering plants, backed by shrubs. If the segment of a circle here shown can have a complete backing of laurustinus, the flowers will have the best possible background; with rather taller shrubs to fill up to the hedge next to the road. The same, or other shrubs, mostly evergreen, will form a screen on the frontier side opposite the garden door. The house on that side should have a Clematis montana, which in time will cover the whole wall. Close against the house foot the planting should be mostly of small shrubs of the rosemary and lavender type and size, with solid angles of box or laurustinus.

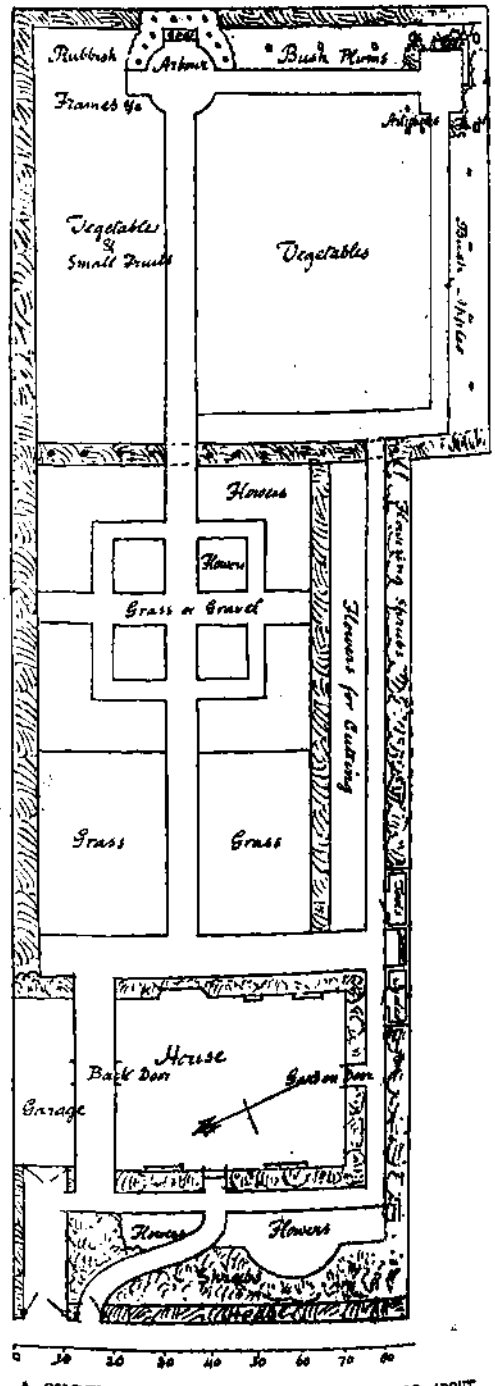
A wide path in front of the house is always desirable. A little range of useful sheds is shown at the southern end. An open space in the middle with a seat will be welcome in summer; another seat for a winter sun-trap can easily be notched into the hedge at the other end of the path, though not shown in the plan. The sheds can be framed of wood on three courses of brick, and can be cheaply roofed with corrugated iron, which requires a very slight pitch; the front and sides should be of elm weather-boarding, which soon turns to a silvery grey. A few battens across the corrugated iron and a couple of plants of the native Clematis Vitalba, will soon hide the iron roof. A front gutter will carry rainwater to a butt, handy for watering the flower border.

A main path down the garden from the principal sitting-room window passes first through a grass lawn and then to a small rectangular parterre. It is optional whether to have this with gravel paths, in which case the beds would be bordered with thin stone on edge, or, preferably, with dwarf box; or whether to have the whole on grass, with the two spaces marked "grass" in one, and doing away with the dividing path. As a matter of design this is the better way and gives a comfortable feeling of less complication. The surrounding hedges can be partly of evergreen and partly of deciduous flowering shrubs, either green holly or oval-leaved privet, with lilacs, guelder-rose and ribes. The hedge next the vegetable ground can be all of rambling roses on posts, rising from a continuous hedge of box, trimmed to something like 3ft. 6ins. high. A light chain, fixed with a staple to the top of each post and allowed to sag about 9ins. down between each post, will guide the roses into hanging garlands.

A border of useful hardy plants, marked "Flowers for cutting," and the flowering shrubs opposite will give a pleasant alternative way to the lower garden

If this is used for vegetables it may none the less have some pleasant features, such as the arbour, with its circular front space and with some slight wooden framework to support a vine, Virginia creeper, jasmine and early Dutch honeysuckle. The square also, with a seat at the south-east angle, is planned for three good shade trees, such as planes, with a square cut green box at the angles opposite the outer trees and a back filling of either common or broad-leaved laurel. There has been some feeling of objection to laurels in gardens of late, that I hope is now being overcome. I wish to point out that the laurel is one of the most beautiful and generally useful of our hardy evergreens. It has, in fact, only fallen into disrepute on account of its merits, because its docile and long suffering character has enabled it to be put to ignoble uses. In this corner if it is planted about 2ft. from the back of the seat, it can be let grow 10ft. high and the upper branches that come forward can be trimmed into a complete hood over the seat. A group of three globe artichokes, one of the handsomest of garden plants, will screen most of the vegetable ground from those using the seats.

If the owners would rather depend on the greenhouse for their supply of vegetables, and wish to give their whole space to pleasure-ground, the larger space marked "Vegetables" would come delightfully as a square green lawn with 10ft. wide flower borders outside and a grassy way out on all four sides. The narrower space marked "Vegetables and small fruits," would make a pretty garden for children.



A SUGGESTED LAY-OUT FOR AN AREA OF ABOUT HALF AN ACRE WITH THE FRONT OF THE HOUSE HAVING A WESTERN ASPECT.

FLOWER GARDEN NOTES

Sweet Williams.

IT is questionable whether sweet williams have ever been more popular than they are to-day, and this is due in a large measure to the introduction of sorts in comparatively recent years which have gained for them a deal of notice. I refer to Sutton's Pink Beauty and Sutton's Scarlet. They created a mild sensation when they were first shown by the firm, and it was not long before they became familiar tenants in many gardens. Like some other old-fashioned plants that were highly prized by florists of a former generation, sweet williams bring much pleasant colour to a garden in early summer, and they are ideal plants for an amateur to take in hand, for the reason that they are perfectly hardy, require no protection of any sort, and will grow in any fairly good soil. They like an open, sunny situation, and are to be looked upon as plants suitable for town and suburban gardens. The time of their blooming is also the period when these biennials can be sown. It should be in a bed in the open that is exposed to the sun, and when the young plants have developed their second leaf, no time should be lost in transplanting them 6ins. or 8ins. apart. In the autumn they will be ready for transference to their final quarters. In doing this, it will be found that the best display is secured if they are grouped —say, three or four plants, giving them about a foot apart. Sweet williams can also be propagated from cuttings, and these should be taken after the plants have done flowering, but as a general rule it is best to treat them as biennials and sow seed every year for blooming the following. There is no gain in permitting old plants to remain on hand, as young ones flower much better.—W. F.

Some Forms of Alumroot.

SEVERAL very fine varieties of Heuchera sanguinea are sold nowadays and growers who love a refined, graceful and free-blooming type of plant may with great pleasure secure a few. Walkeri is one of the best, a rich crimson and very free; Edge Hall is rose coloured; Pluie de Feu, a fiery red; grandiflora, a large-flowered red; and Rosamond, a coral pink—all of them delightful. The species gracillina is also good; the graceful panicles of rose tinted small flowers are of high decorative value. The popular brizoides is better known for its foliage, a prettily marked evergreen, but I like better a variety of it known as Elsie, in which the flowers are a much more distinct and striking colour. Of others I prefer Nellie, an effective spike for table decoration; Red Indian, too, must not be omitted, because nothing else in the garden has that peculiar colour; Zabeliana, another rich rosy-red of great beauty; lucida and erubescens, both fairly good whites, light, feathery and fine in vases; Heucheras like a light loam and will be found to do well in a sunny border or in the rock garden. —LANARKSHIRE.

Pinks in the Modern Garden.

THERE is scarcely any plant in the garden of lowly growth the culture and propagation of which are so simple, or one that is hardier and yields so lavishly its deliciously sweet-scented blossoms as the homely pink. Said a friend to me a few months ago, "You see, I have planted pinks as an edging; they have been glorious, and give no trouble, except to strike what cuttings I want." Exactly; that is where pinks count to-day. Provided the ground is dug where they are wanted to grow, and a little sand is incorporated with it, should it be at all heavy, one may dibble in the cuttings as soon as the flowering season is over. Cuttings are best taken at a joint where the wood is ripest, pinching off the tips of the leaves, and planting firmly. In arranging for an edging of plants near the pathway, it is important that the soil should be well dug, as very often there it is sad and heavy. Especially is this so in borders that may be fringed with spring-flowering bulbs, where, for fear of disturbing them, the soil is seldom interfered with. One advantage about pinks is that for a couple of seasons it is seldom necessary to molest them. In country gardens, pinks have ever been favourites, but they are not the special perquisites of the country, for in both suburban and town gardens the veriest tyro may succeed with them if he will only start on the lines suggested. Once cuttings have been put in and commence to grow, they need no protection; cold weather will not hurt them, and very severe frosts take little toll from them. Let me warn the new grower of allowing his plants to continue for years without working up a fresh stock. Young plants flower the best, and should be dealt with from the point of individual plants and not permitted to develop into miniature beds or "rings," which invariably means that they take up room belonging to other plants in the borders. It is when pinks are allowed to go their own way for years that the centre of the bed or "ring" begins to show sign of canker. Only from healthy, vigorous plants should one attempt to take cuttings.

Their Place in the Modern Garden.—The modern gardener is alive to the importance of growing plants to yield plenty of flowers for cutting. He will never do wrong in including pinks in his arrangements. Sorts of comparatively recent introduction are now available and have been the means of focussing attention on some of the older forms.

Varieties.—In old sorts much esteemed, one thinks of Mrs. Sinkins, a very popular one, rich in perfume and yielding flowers in plenty. It is a white, worthy of inclusion in any garden. Other good whites are Her Majesty, Albino and Fimbriata, Ernest Ladhams (blush white with carmine centre), Homer (red with dark zones) and Sam Barlow (white with centre of claret), all good.

Laced Pinks, loved of the old florists, have a more limited patronage. One thinks of old stalwarts like The Rector (white and rose) and Old Chelsea (rose and red).

Allwoodiis.—No collection of pinks to-day, however, can be considered complete if it does not include Allwoodii. The colours are delightful, the flowers are so dainty and charming, and so very freely borne withal, over a longer season than most pinks bloom, that it is a foregone conclusion they have come to stay, particularly so when we remember how hardy they are. Every year many more are won over and captivated by their beauty, so that their culture is largely on the increase. One does not need to give a long list of the sorts now in cultivation, as many hardy plantsmen stock them to-day.

The following are but a fraction of the varieties. Some are among the earlier introductions, and their prettiness warrants their retention: Peggy, mauve maroon; Lottie, salmon self; Rufus, bright rose; Maud, delicate salmon pink; Dorothy, deep rose pink; John, deep rose and maroon; Susan, pale lilac, dark centre; Eleanor, white and pink.—W. LINDERS LEA.

PINKS ARE AMONG THE FINEST OF OUR PLANTS FOR GENERAL EFFECT IN THE GARDEN.

The Shrubby Jerusalem Sages.

WE might, I consider, make more use of the phlomises, or Jerusalem sages, as they are generally of bold and uncommon appearance and add considerably to the effect of a garden when properly placed. Of the various species in cultivation some are shrubby and others herbaceous, and it is generally conceded that Phlomis fruticosa is the finest of the shrubby ones. Its hardiness is sometimes called in question, and there is no doubt that it may be tender in very cold localities. In the south-west of Scotland, even a good distance from the sea, it is hardy enough, and I have grown it successfully in a poor soil in a rather dry situation well exposed to the sun. It may be confidently recommended for southern gardens. It is a most distinct plant at all times. It forms a bush some 3ft. or 4ft.

Digitized by Google

high, as a rule, although I have seen it a little more than the latter height. It has large leaves, covered with a peculiar rusty down, which gives the plant a character of its own. Then it bears whorls of large yellow flowers, foliage and flower associating well and combining to produce the effect alluded to above. It may be employed either in the herbaceous or the shrubbery border, and in either it is quite a good plant. It should not, however, be crowded up by other plants of much the same or greater height, and it looks best rising through some low carpeting subject. It flowers during June, July and August. I may add that it does not appear to transplant readily when of any size.—S. ARNOTT.

The Decorative Bear-berry.

FOR covering unsightly corners or large stones on a rock garden this plant is recommended. It is a native of this country, being found in the north of England and Scotland, but a very fine form of this species is known as Arctostaphylos californica, which hails from western America. It is a trailing evergreen of somewhat vigorous growth, with small, leathery leaves and white flowers which appear during July and August. Its chief beauty, however, will be found in the red berries, which are freely produced, and they are exceptionally bright from September onwards. To be seen to the best advantage it should be planted on an elevated position, when its long, trailing, evergreen growths will gracefully drape a rugged and perhaps an ugly rock. It is also well adapted for covering isolated stones on the outskirts of the rock garden. This plant is readily increased from cuttings, layers and seeds.—B.

A White-Berried Shrub.

IN Hymenanthera crassifolia we have a shrub which attains a height of 4ft. to 5ft., and often twice as much through owing to its low-growing habit. It is most conspicuous among berried shrubs on account of its white berries. These are produced in profusion, and remain on the plant during the autumn and well into the winter months. The branches are rather stiff and somewhat angular, these being covered with ash-coloured bark, while the inconspicuous flowers are brownish in colour. The leaves are thick and leathery, about ½in. long and very numerous. It is, however, its beauty as a berried shrub that makes it noteworthy, and it is interesting to know that it belongs to the Natural Order Violaceæ, therefore is a relation of the pansy and viola. This plant is quite hardy, and can be increased by cuttings or seeds. It is a native of New Zealand, and was introduced about 1875.—T. W. B.

Wallflowers: The Most Effective Way of Planting.

IN most gardens where plants for a spring display are grown, wallflowers are now looked upon as not the least important, their diversity of colour coupled with their sweetness gaining for them hosts of admirers. Opinions differ, possibly, as to what is the best plan to adopt in November when the bulk of plants are removed to their final quarters, but it seems to me, if one desires the most pleasing and effective results, this is only obtained when they are planted out in groups of separate colours. From a mixed packet of seed one can have plants, vigorous and with half the trouble in keeping each colour group to itself, but for the sake of trouble it is worth while ensuring the charm and distinctness in a garden by growing varieties by themselves.

For a number of years I have followed the colour grouping plan, and as the wallflowers bloom contemporarily with May-flowering tulips, which are also planted in little colonies of one colour, the result, to me, is much more satisfactory than any mixed arrangement could possibly be. The sorts I have planted this autumn are Purple Queen, Faerie Queen, Eastern Queen, interspersed between glowing colours of Blood Red, Cloth of Gold, Sutton's Orange Bedder, and Sutton's Fire King. The last named is one of the most vivid tinted wallflowers of recent years and never fails to excite the admiration of those seeing it for the first time. If I am asked to describe its exact colour, I suppose I should have to say that it is an orange red, but that would give a poor and inadequate idea, as, seen with the sunlight streaming upon it, the spikes of bloom are a warm, glowing mass—a fire colour, if you will. To see it at its finest it is undoubtedly the best plan to plant out in groups, and my long experience with these, the sweetest of spring flowers, prompts me to say the same about the older sorts too.—W. LINDERS LEA.

AUTUMN TREATMENT OF RAMBLER ROSES

ALTHOUGH it is generally known that rambler roses should have some of their old growths cut out in autumn, there are quite a number of novices who seem to be uncertain how to proceed with this work.

It will not do to treat all ramblers alike. There are practically two distinct types, those of the multiflora group, such as the old Crimson Rambler and Blush Rambler, and those of the Wichuraiana group, such as Albéric Barbier.

With the multiflora group it is best to cut out most of the old wood each year, as they produce finer trusses of blossom on the rods or growths made during the current summer. It may not be practicable to do this the first year, unless the plant has made good new shoots, but as the plants age then there will be no difficulty. It sometimes happens that an old growth will produce a young vigorous shoot some 3ft. or 4ft. from the base, in which case it would be folly to cut away the old growth.

In dealing with the Wichuraiana hybrids, perhaps I should explain that these are readily recognised by their longer and more slender growths, very willowy in appearance, and usually having lovely glistening foliage. The two and three year old growths of this tribe are frequently in a very healthy condition, and there can be no excuse to cut them away excepting for want of space. For instance, one may see a house or wall completely covered with a single plant of Albéric Barbier, and the plant seems so full of vitality that it would be folly to curb its activity by removing old wood. As soon as there appears a sign of deterioration or weakness in growths springing from the old wood, then this latter must be cut away. It is when ramblers are growing upon arches or pergolas that strict watch must be kept upon them, or we find there will be no young shoots produced from the base, and very soon we shall have an unsightly tree. To guard against this, it should be a practice to cut away the old wood freely, especially that which emanates from the base of the plant. By so doing we encourage new shoots to maintain the juvenile condition of things. One should not cut away an old growth if by so doing a bare space is left. There are

A WELL GROWN RAMBLER ROSE.

some of the Wichuraiana roses, such as Paul's Scarlet and American Pillar, that more nearly resemble the multiflora group in their somewhat rigid habit, and to these we must apply the more drastic cutting out of old wood. In removing this old wood, cut down as close to the ground as possible then in course of time we shall be rewarded by fine strong basal shoots that will carry on the flowering.

It should be remembered that finer trusses of bloom are obtained from the new shoots retained, and it is unnecessary to have too many of these shoots on one plant. Three or four good strong rods produce a finer display than a whole host of small twiggy shoots.

This thinning-out process may be done at once—in fact, it is a good plan to carry it out as soon as the flowering of each particular variety is finished. Although that is not always practicable owing to more urgent claims on our time, the earlier it is done in autumn the better; then the young growths retained are assisted in their ripening by the more abundant air and sunshine admitted to them.

I should point out that the amateur must not make the mistake of cutting the lateral growths now. This must be done in March. If an old growth or two are retained, having good strong laterals, these laterals, if cut back in March, will yield far finer trusses than if left long or even unpruned, as is too often the case. If there was a more severe pruning of these lateral growths we should see far less mildew and insect pests which despoil so many ramblers in the average garden.

When rambler roses are budded upon tall briars to form "weeping" or "shower" roses, their pruning should be on similar lines. As soon as flowering is over, cut back old wood close to the crown of the tree. Probably by this time the new growths are not fully developed, but by late autumn they will have grown abundantly in length. W. E.

Dual-Purpose Apples.

HERE is a short selection of apple varieties which are suitable for dessert as well as culinary purposes.

Annie Elizabeth.—This variety is not so well known as it should be. Generally classed as a cooker, it is quite good for dessert purposes in April and May. A strong, upright grower and a regular cropper. The fruit is large, round, oblong and of golden yellow colour when ripe, with a bright flush on the exposed side.

Beauty of Kent.—The fruit is large, conical, striped red on a yellow ground. The flesh is tender and with an acid flavour. It is a strong grower and a good cropper. Season November–March.

Blenheim Orange.—One of the best known of all apples. It is sometimes shy bearing when young. It is a strong grower and makes huge spreading trees. The colour is yellow, striped and flushed with red and russet. Season November–January.

Charles Ross.—Although a cooker, it will keep for dessert at Christmas-time. Only very large or malformed fruit should be used in the kitchen. The flesh is tender, sweet and of good flavour.

Cox's Pomona.—A large flat apple, streaked and flushed red. One of the most prolific of apples. Its season is from October to February.

Duchess of Oldenburgh.—This is quite a useful variety for culinary or dessert purposes. It is an early apple, its season lasting from August to September. The striped fruit is handsome, but rather small. This variety bears well.

Gascoyne's Scarlet.—Large, oblong, attractive fruit of rich crimson. The flesh is tender and crisp. Season December–February.

Newton Wonder.—This variety is most useful in the kitchen, but can be used for dessert in March. The fruit is of medium size, round, flushed and striped with scarlet. Very heavy cropper, strong and vigorous grower. Flesh crisp and acid. Season, December–May.

The Window Garden.

DURING the rapidly shortening hours of daylight from November onward, window plants need all the light they can get, but due protection must be given from frost if it is likely to be severe. A few sheets of newspaper make a good frost shield, if placed between the plants and the glass. Paper is also useful to give some protection from cold draughts when the window is open.

Airing is necessary. Even in the coldest weather the plants should have a little fresh air. In very mild weather the plants may be given a shower bath, in the form of a fine spray. Palms and other foliage plants may be lightly sponged.

During very severe frost, it is advisable to remove tender flowers from the window and place them on a chair, or on the floor, with some tissue paper thrown over them. With such treatment at night and by keeping the plants as near the glass as can be done with safety during the day, a very choice selection of fine window plants may easily be grown.

Watering at this season must be done with care and attention. Only when the plants are really in need of water should any be given during frosty weather. Stagnant water must not be allowed to stand in the saucers. Watering is best done during the early part of the day and tepid water should always be used. In potting use a good fibrous loam, with some fine peat or leaf mould, well rotted manure, and just enough sand to suit the soil used.—J. W.

Crocuses in Grass.

EVEN the middle of November is not too late to plant many of the spring-flowering bulbs, and as these can often be procured at a cheaper rate now than earlier in the season, larger quantities can be afforded.

To secure the best effect in grass, crocuses should be scattered in handfuls and planted

CROCUSES ESTABLISHED IN GRASS.

where they fall, carefully replacing the turf after planting. By following this method a natural effect is obtained. Plant 4ins. deep, and if it is possible to place some good soil in the holes along with the corms so much the better. One colour by itself, or, at the most, two together, is to be preferred to a general mixture of shades. Crocuses should only be planted where there is no objection to leaving the grass unmown until after the foliage has died away.—T. H. E.

A Good Bedding Arrangement.

THE following is a good plan for obtaining a continuity of bloom with a minimum expenditure of labour and cash.

Prepare a bed in the autumn by deeply digging and if the soil is of a light nature, work in a good layer of well rotted manure, if of a heavy texture, use some lighter material, such as strawy manure or leaf soil. Any time before December plant bulbs of Spanish iris at a distance of 9ins. apart, and either in the autumn or spring according to the locality and situation, plant a carpeting of violas. Yellow violas go well with blue iris or *vice versa*. Choose a suitable opportunity between mid-March and mid-April and plant corms of the beautiful primulinus hyb alternately with the iris.

The iris make a splendid sho then follows a brief period whe have the field to themselves an gladioli give of their best. The iris should be allowed to die down they may then be used success H. E.

Double White Arabis Pot Plant.

UNTIL the advent of the dou arabis, the idea of potting u sort for bringing into bloom ea thought of, but A. albida fl. pl spikes of bloom lends itself to and if subjected to the shelter of one may have the flowers in adva out of doors. Young plants from cuttings last spring after th had bloomed will be found co potting up forthwith. Any li suffice and the better plan is to p a cold frame or cold greenhous have established themselves. forcing this arabis is not s anything like a great heat woul object; rather is it better to lu into bloom by introducing them warmth. The spikes come a under glass, and may, if need them more erect, be tied to thin which is all the support requi should be kept on a shelf not from the glass, and not allowed water once the buds show.—W

OF BABY JACK, A SMALL-FLOWERED SINGLE VARIETY. ERS FREELY DURING NOVEMBER. IT SHOULD BE . GREENHOUSE TREATMENT

SOME MODERN CHR

Few of our autumn or winter flowering plants give such a long display of bloom or are so useful as the chrysanthemums. Early border varieties first show their bloom in August, mid-season types are at their best in the cold greenhouse during October and November, while in a warm greenhouse the last flowers of the late-flowering Japanese varieties do not fade until the second or third week in January. Modern varieties are almost as varied in form as the dahlia, and these newer introductions are of clear, bright self colours, as well as combinations of most artistic shades of bronze and gold, rosy mauve and purple, and apricot yellow and rose. Early-flowering types, which consist of both single and double varieties, will bloom outside from August onwards. Among the doubles are Lichfield Bronze, Nina Blick (orange red), Phœnix (scarlet bronze), Pluie d'Argent (white), September Yellow, Pink Profusion and Harvester (amber). A few good early-flowering singles are Niobe (yellow), John Woolman (pink); Shrapnel (terra-cotta), Doreen Woolman (flame), and Stanley Baldwin (deep crimson).

OME CHRYSANTHEMUMS

Early pompons, with their dainty little button-like flowers, are also suitable for a border outside. The next chrysanthemums to flower are the mid-season decorative varieties. These are best grown out of doors during the summer months and then lifted and planted in a cold greenhouse. Cranfordia is a well known bronzy yellow, Source d'Or a terracotta, and these, with Yellow Moneymaker and Uxbridge Pink, are all easily grown. From November onwards chrysanthemums in heated houses begin to bloom. Decorative Japanese varieties, which can be grown for large blooms or left as sprays, form the largest class. New varieties, such as Aldyth, Harmony and The Wizard are striking in colour. Some of the modern single varieties are of immense size, with long reflexed petals, and are remarkably wide in colour range. Baby Jack is one of the small-flowered kinds, R. Blyth, Molly Godfrey and Charming are three of the best large-flowered varieties. Incurved varieties and large exhibition varieties, with their huge heavy heads of bloom, need careful culture and always attract considerable attention.

Fruit is Gathered.

people forget the fact that a tree as borne a heavy crop of fruit less exhausted and needs some uperation—that it is in a similar that of the human who is "run r a spell of hard work and who liday and good food to restore

A MULCH OF STRAWY MANURE THE ROOTS OF A FRUIT TREE.

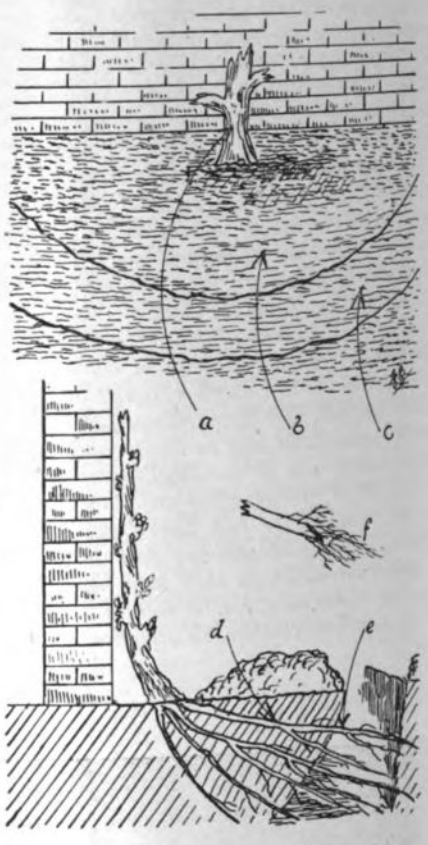
n the case of the tree it never for no sooner has the fruit matured rgies are centred upon the develop- ext season's fruiting buds. The may not provide adequate nourish- the fruit grower will be wise if recuperation by giving the tree This is best effected by a mulch ed manure or a mixture of strawy material, poultry or other manure, soot and wood-ashes. It is true that the leaves fallen from the tree have provided Nature's mulch, but the tree will be all the better for the additional manurial material. Old soot and ashes from the smudge fire can be beneficially applied alone and lightly forked into the soil for a few feet around the tree, especially where there are plenty of leaves to dig in as well.

The Earliest Peas.

THE treatment of these is very much like that of the broad bean, but the young plants need more care in their raising and general treatment, through a severe winter. For this reason a brief separate note is devoted to their culture. In some gardens the soil is, naturally, a heavy, cold, clayey loam. Where such obtains, the cultivator must go to a little extra trouble in procuring rotted leaf-soil and such as is turned out of pots and plant boxes. All this material should be collected and passed through a 1in. mesh sieve. The ordinary garden soil is prepared in the usual way, but where the rows of peas are to be, it should be raised about 3ins. above normal level. Open out shallow drills quite 6ins. wide; scatter a layer of sifted compost in the drill, sow the seeds—after rolling them in red lead—1in. apart, cover them 2ins. deep and place a layer of ashes, not too fine, on the surface. Just bury them from sight with the sifted soil before adding the garden loam. Draw up soil to each drill and forthwith stick the rows, using, at this stage, only the dwarf sticks. Later on, if the frosts are severe after the plants are well up, stick also with a few evergreen branches, especially on the north and east sides. Only early round-seeded varieties should be sown, as even the earliest wrinkled-seeded sorts will rot in the soil. Of course, the warmest spot in the garden is not too good for our few rows of early peas.

Preparing Specimen Fruit Trees on Walls for Lifting and Root-Pruning

FRUIT trees, in some soils, grow normally and bear fruits freely without any special attention being devoted to them. Others grow slowly and require good feeding, while there are some that make very strong growth and do not fruit satisfactorily. Space on walls is too valuable to be wasted and so every specimen fruit tree occupying such space should be so managed that it will be a profitable one. Owing to the fact that nearly all the roots grow at right angles from the wall, root-pruning should not prove to be a difficult operation. Operation it is, and there is only one right way of carrying it out. November is a suitable month in which to do the work, but it may be commenced late in October. If growers, who intend to root-prune some of their unsatisfactory trees, will carefully examine the accompanying sketches the latter will be helpful to them. The stem of tree at 1ft. above soil level, *a*, measures 4ins. across, it is, perhaps, ten years old. The distance from the wall to the edge of the proposed trench should be approximately 3ft., shown at *b*. The width of the trench, *c*, should be 18ins. to allow the workman ample space to move in. At *d*, the roots are shown growing in a downward direction, and almost fibreless. When the trench is being opened—in a slanting direction under the roots—the strongest, shown at *e*, should be cut off with the aid of a sharp knife. All small, or fibrous roots bared must be retained intact and be kept moist while they are exposed to the air. Immediately the root cutting is finished the trench should be filled up with the original soil taken out and some nice gritty loam added. In the case of all stone fruits it will be beneficial to the trees if some old mortar rubble is also mixed with the soil. Failing mortar rubble, use half a bushel of slaked and cooled lime, dried and broken, so that it can be evenly mixed with the soil generally. Make the new soil



very firm by treading as it is put into the trench. The ends of the cut-back roots should afterwards become furnished with fibrous ones in great numbers as shown at *f*, then the grower can readily feed his trees and so cause them to form fruit buds and fine fruits. If any specimen trees are to be lifted and replanted in a new position it is best to trench round them this autumn; sever some of the strongest roots and refill the trench. Next autumn the tree may be successfully moved.

The Morello Cherry.

THE Morello cherry is a tree which grows luxuriantly, more particularly in sites that are not suitable for the general run of fruit trees. It is invariably advocated as a suitable tree for north aspects; it also does exceedingly well in east borders which are often looked upon as hopeless for fruits. The fruits of the Morello are of an acid nature and not readily attacked by feathered marauders, so that it is a fairly safe crop where growers are troubled with these voracious pests. When planting the trees about this time do not omit to trench the ground to a good depth and to bury plenty of leaf-mould and soft rubbish in the second spit; also give a fair dressing of good manure or manure substitute to the upper spit. Lime the ground well also. Chalk or carbonate of lime is better than quicklime, but slaked lime weathered for a few days can be used. Lime is most essential to this fruit. Established trees repay kindly treatment in regard to annual manuring. Small trees from the nursery will carry fruit the first year, but this should be picked off to get good growth established.

FLOWERS UNDER GLASS

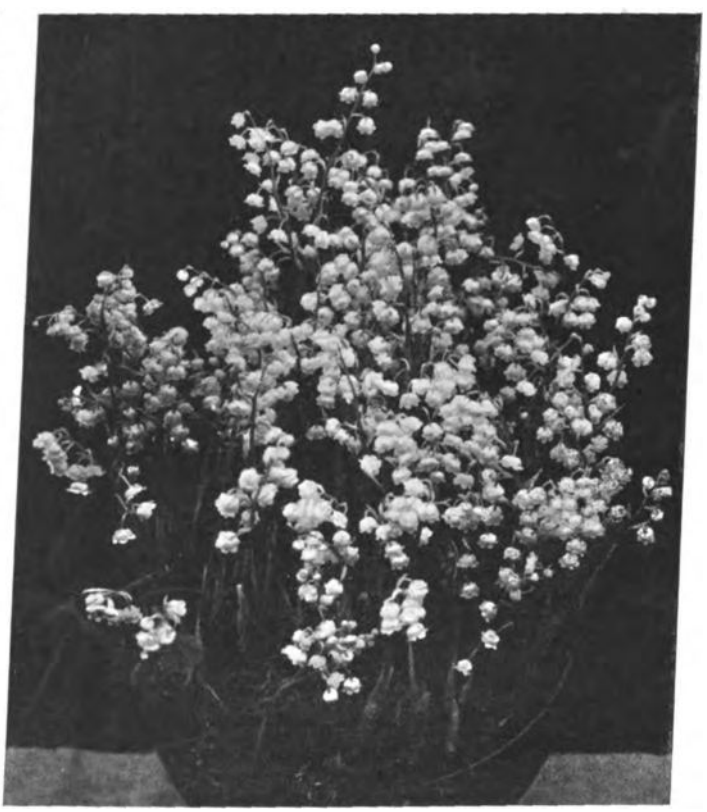
Growing Retarded Lilies of the Valley.

QUITE a number of people hardly realise the ease with which retarded lily of the valley "crowns" (as the roots are called) may be grown. Of course, these roots, which would in the natural way have grown last spring, have been kept back in a refrigerator and will rapidly break into flower and leafage even in the temperature of an ordinary living room. A few of these retarded crowns form an interesting addition to the room garden and with ordinary care, success is certain.

For many years the writer has grown a few batches for Christmas, and a few hints from his personal experience may be helpful. The crowns may be grown in soil, but fibre is cleaner and quite as satisfactory. Pots are better than bowls on account of the free drainage which they give to the plants. Spread the thick roots out as much as possible when planting, and allow the pink shoots at the top to be quite clear of the fibre. If the fibre is moist at the start, do not give any water for a few days. Keep the pots in some well shaded place for ten days or a week. If the temperature is well maintained the crowns will by this time have started. Then the plants can be removed to a lighter position, but it is a mistake to stand them in a sunny window. Lilies of the valley are naturally shade lovers, and they are apt to be rather stunted and poor when the light is very strong.

As the lilies grow, more water will be required. Always give this lukewarm, as absolutely cold water will impose a severe check on the plants. The way in which the lilies develop their flowers and foliage is almost magical, and those who have not grown retarded crowns before will be surprised and pleased.

If planting for any special occcasion, such as Christmas, some thought should be given to the time which is to be allowed for growth. In a living-room it is easy to have the lilies in full beauty six weeks from the time of planting, and often the period is several days less than this. One thing is to be guarded against, and that is never allow the lilies to be exposed to draughts or really cold air. The writer used to remove his lilies to the kitchen during the night, as here the temperature was sure to be well maintained.—S. L. B.



A BOWL OF LILIES OF THE VALLEY MAKES ONE OF THE MOST CHARMING OF INTERIOR DECORATIONS.

Violets in Frames.

IT cannot be said that the culture of violets in frames outside the profesional domain finds many adherents. Amateurs, I think, rather begrudge giving them such a shelter, preferring to use their frames for wintering half-hardy plants that will serve them another summer. In view of the simple requirements of these exquisitely scented flowers, it is a pity that more do not make an attempt to provide accommodation during their period of blooming, for that is practically all they ask in the way of glass protection. Then, again, one meets with those who persist in looking upon them as less than hardy, and so when they have removed their clumps to frames, forget to give them abundance of air whenever the weather serves, and, consequently, damping off takes place rapidly, and their view about growing violets in frames undergoes a change and they become disheartened. This is not an imaginary picture, but one which may be seen almost every season. It is well perhaps at this date to refer briefly to methods which, if carried out, lead to success. Runners of violets should be taken in April from crowns that have flowered. These should be planted in a bed 12ins. or even 18ins. apart in soil in which some well rotted manure and leaf-mould has been incorporated. It is important to note that the best position is on the north side of the garden, but not necessarily among other flowering plants, as one can often find a spot between vegetables that will serve admirably, as, for instance, between rows of runner beans or peas, where sufficient shade is secured.

In shifting the clumps in September as much soil as is possible should be lifted also in order to disturb the roots as little as possible, and after giving them a soaking of water, shade ought to be afforded them should the weather be sunny, the main idea being to avoid a check. A free current of air both top and bottom in frames where violets are located is essential, and in watering the plants it should be done in the morning, at the same time removing all dead and decaying leaves, stirring the surface of the bed and so avoiding the continuance of damp. In a rainy period when the lights are kept on the question of ventilation must not be overlooked, and a little sulphur dusted about the plants will act as an astringent and do much towards keeping the plants free from damping off. For the encouragement of the tyro, however, who may be disheartened at seeing some of his plants losing their leaves owing to damp, it may be said that violets have such recuperating powers that new leaves soon follow, and though blossoms may be retarded for a time, they come eventually. In the spring, when flowers have gone, the work of propagation should be got on with, selecting the first runners. While plants are in frames all such runners should be discouraged during the blooming season.

Sorts worth recommending are: *Doubles.*—Comte de Brazza, white; Marie Louise, mauve; Neapolitan, lavender blue; and Mrs. J. J. Astor, pale rose. *Singles.*—La France, violet blue; Princess of Wales, purple blue; White Czar; and Admiral Avellan, reddish mauve.—CLAREMONT.

Storing Summer Bedding Plants for the Winter.

WHEN we look at our flower borders from time to time during the summer months we do not always think about the winter treatment of many of the plants.

Such kinds as zonal pelargoniums may be safely laid in in a cold frame or even at the foot of a wall or fence for a few days and be quite safe there if covered at sunset each day. In the meantime the pot-grown plants can be dealt with. In these days when many beds are made to resemble groups of plants, formerly seen so placed in our greenhouses, the subjects are mostly retained in their pots intact. So it is only necessary to lift the pots from the soil. Many will have produced roots through the drainage holes in the pots or over the rims. Such roots will be sacrificed in due time; do not remove them at the time of lifting. Usually, these plants may be placed in a shed for a week or so. Each morning syringe the pots and protruding roots. Mostly the plants will be those of fuchsias, lemon-scented verbena, scented-leaved geraniums, abutilons, heliotrope, plumbago and bougainvillea. If convenient, transfer the abutilons and heliotrope to a greenhouse temperature as soon as possible. Then there are the bulbs and tuberous-rooted subjects; these should be lifted with both tops and some soil adhering to them. At once place them in boxes in rows, laying down all tubers facing one way, the tops in the opposite direcion. The ideal place for these plants for about one month is a peach-house with plenty of ventilation, a cold frame, also freely ventilated and matted at night, or an open, dry shed where mats can be placed on the tubers at night. In the meantime the energetic worker is engaged in completing the planting of the beds with bulbs and spring-flowering subjects. He should then turn his attention to the temporarily stored plants and tubers. Zonal pelargonium leaves and stems soon decay if overcrowded, so these should be dealt with first. Strip off all the large leaves, shorten the roots, have some dry soil sifted, crock some large pots, place quite half a dozen old plants in a 9in. pot and fill up with the fine soil. Treat the fuchsias, verbena and bougainvillea, also the plumbago, in a similar way, fewer plants to a pot if necessary. Water thoroughly once, then store in a peach-house. Very little water will be needed during the winter months.

WHAT OUR READERS SAY

PERENNIAL SCABIOUS.

SIR,—"E. S." asks if any reader has tried the experiment of keeping scabious for a third year. In this garden, on the Sussex coast, I have come to look upon the scabious as quite good perennials and I have several plants which are now five years old and are still going strong. However, after the third year the root stock becomes woody and is apt to rot during a wet winter like the last. The old plants start to flower at the end of June and, in a favourable season, continue well into November. When going over the borders in autumn, I cut down the plants to within about 8ins. from the ground and leave them where they are, forking around them and keeping a look-out for self-sown seedlings, which, when found, are transplanted.

Some time ago a correspondent threw doubts on the perennial qualities of Geum Mrs. Bradshaw. I have some plants of this which are more than ten years old and which are the picture of health; with me it is one of the most reliable of perennials. On the other hand on this ground, a somewhat heavy loam, I can never rely on a lupin after the second year, unless divided and planted in fresh ground.—H. R. HANNAY, *East Sussex.*

A VARIETY OF BEAUTIFUL HABIT.

THE MODERN DELPHINIUM.

SIR,—In the issue of THE GARDEN, dated October 9th, on page 567, there appears an illustration of a Delphinium which you describe as "The Stately Delphinium." I cannot resist sending you the two accompanying illustrations of what I should describe as "Modern Delphiniums."

The first variety illustrated is known as Welsh Fairy, a blue self with a small black eye. The plant has a fine habit, and there appears to be a great deal of "wire" in the composition of the stem of this plant as in a primulinus gladiolus. It will blow about with the wind and will come back to the same place without breaking. The second plant carries violet flowers with a soft brown eye. It has a good habit but the "pips" are not sufficiently large.—WATKIN SAMUEL, *Wrexham.*

ERICA ST. KEVERNE AS AN EDGING.

SIR,—In your issue of October 16th you recommend Erica St. Keverne as an edging plant, a suggestion which, I am sure, has only to be acted on to be appreciated by many who have never thought of heaths in this connection.

I have vivid memories (alas, thirty odd years old), of the gardens of Carradale House, Argyllshire, the extensive paths of which were edged with a close-growing white Erica vagans and anything more delightful and durable for the purpose I have not seen since.

St. Keverne or Mrs. D. F. Maxwell, both of which do well here, would add the charm of their excellent colour, but getting stock quickly enough is my trouble.—GEORGE L. CRAIG, *Thongsbridge.*

THE TREE OF LIFE.

SIR,—When I was in the West Indies I picked some branches of the tree of life, left them lying about, without water, in my cabin coming home, and then picked off some leaves and laid them on the mantelpiece. They all started to grow well, making quite good shoots without water. I then potted them and grew them like geraniums, but mine never flowered. A friend who was with me, after potting, put hers in a stove, and the heat made them flower splendidly and very effective they were. I do not know the correct name, it is always known as the Tree of Life in the Barbadoes.—N. S. C., *Godstone.*

DOUBLE POLYANTHUS AND DOUBLE PRIMROSES.

SIR,—For some time past there has been steadily growing an awakening of interest in old-world plants and more especially in the old-fashioned primroses and polyanthus—learnedly classified, and usually many absent, under the head of primulas. I venture to write on this subject as Ireland was the home of many old-time favourites and is now nearly the last stronghold of many of them, owing, I think, to our soft, mild climate. I have been able to

A PLANT OF GOOD HABIT, BUT THE "PIPS" ARE NOT SUFFICIENTLY LARGE.

make a small collection and it may be of interest to describe some of them. First, I hold the least important, but nevertheless quaint and interesting, Hose-in-Hose, with one flower tube inside. Another of these in primroses I have is white (or rather cream), and one, a clear yellow. I know of a red also. Of Hose-in-Hose polyanthus I have a brown and greyish, laced brown and yellow, bronze and yellow and a purple laced silver. Of double polyanthus I have Tortoiseshell, which is a bright brown and yellow; Rex Theodore, dark brown and yellow; and Harlequin. I think there is not much difference, if any, between Rex Theodore and Harlequin. Curiosity is a pink and yellow and very pretty; Prince Silver Wings, a purple, silver laced and I believe very rare now; Dercloughi has not yet bloomed with me. Of the double primroses, Mme. Pompadour, that lovely velvety crimson, is the most sought after and the hardest to increase, being a very slow grower. A. de Moullin, is a bunch primrose, deep violet. Marie Crousse is also a violet-edged white, and another is the old mauve primrose, also called the evening primrose, because all purples look better in the evening light. French Grey describes itself, as does also Double Sulphur and Double White. [illegible] is a deeper, slightly [illegible]

Latest Yellow I still look for. Burgundy is reddish purple, almost crimson. Sanguinaria plena and Sanguinea plena may be the same. Paddy is an old Irish red. There is an old Irish green; I only know one vendor of it, and this green I have not yet got. Now as to culture. I find they thrive and bloom better if divided soon after blooming and before the soil becomes too dry, also give a good soaking when planting. If divided much later, the plant breaks up into more divisions, but neither thrives nor blooms as well. I work in some peat mould round the plants and find they like it.—E. D. H.

ASTER FARRERI.

SIR—I have been very successful with Aster Farreri. I grow it near the top of a rockery bank, very dry; it flowers and spreads well. I have had to divide it again and again as it runs into its neighbours. It likes good leaf-mouldy soil. No doubt it is far the best of the asters. A. alpinus is half the size and does not flower as freely. I find, of the rather bigger ones, Thomsoni is most satisfactory, about a foot high, very neat and looks well in the rockery, and is useful as a late flowerer.—N. S. C., *Godstone.*

SIR,—Your correspondent, S. Arnott, may be interested to hear that Aster Farreri flowers here profusely at the foot of a dry wall with direct south aspect, high up on the hillside and about 500ft. above sea level. It is planted in good loam in the wall itself.—E. H. RASPIN, *Ilkley, Yorks.*

AMARYLLIS BELLADONNA.

SIR,—My experience here this season with Amaryllis Belladonna has been the same as Mr. Woodall's. I have never before seen such a wealth of these lovely and fragrant flowers, but I can offer no explanation of the cause. Our cold soil last winter was anything but favourable for its growth and weather conditions right up to September seemed far from ideal for ripening the bulbs, but may have enabled them to rest more completely than usual. We have two forms of this amaryllis here, one having broad petals of a light colour, blooming through September, the other, with narrower petals of a deeper rose, blooming later. I photographed fine groups of this on October 17th and in one case four immature spikes were to be seen rising from one bulb. Two days later they were destroyed by 10 degrees of frost. I enclose one of these photographs for your inspection.—H. C. WOOD, *Lingfield.*

A FINE GROUP OF AMARYLLIS BELLADONNA FLOWERING IN OCTOBER.

HOLLYHOCK DISEASE.

SIR,—In reference to your reply to "M. G., Guernsey" (THE GARDEN, October 23rd), on the subject of this horrible disease, may I say that my experience tends to contradict the theory that growing too long on the same site is a contributing factor. Ten or twelve years ago I planted an irregular piece of my garden with single hollyhocks, grown from seed obtained from healthy plants in a garden twenty miles away. The light soil was manured but not heavily. For the first two or three seasons nearly all the plants were very badly diseased, some killed outright and those that lived and flowered, terribly disfigured by the blotched and blackened leaves. But as I specially wanted hollyhocks in this situation for the sake of their decorative effect, I left them there and each year since the disease has become less, until, although never entirely absent, it has been negligible for the last two seasons and I have had a splendid show of bloom. The plants seed themselves freely, some die off each winter and are replaced by the young ones and they are given a top-dressing of stable manure every year.—R. E. H., *Bath.*

HINTS WORTH REMEMBERING

This is a further instalment of Hints that have been received from our readers in response to our request. There seems little doubt, judging from the numbers that have reached us, that this will prove a most useful feature of THE GARDEN *in future. We hope, therefore, that all our readers will assist to make this page as valuable as possible by sending in their Hints, the result of personal observation and trial, and so help the gardening public in general. Hints which will be specially considered as worthy of a prize will be those that are seasonable as well as interesting and apply particularly to duties that can be carried out in the garden at the present time.*

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Each must be sent in on a separate sheet and must not be more than 300 words in length.

THE HALF-GUINEA HINT

How to Insure Peonies Against Frost.

When tidying up the herbaceous border, do not cut off all the old stalks and leaves of peonies. Turn down five or six stalks with leaves outward, thus forming a tent 9ins. or 10ins. above the plant's growing centre. Tie round with bass. This insures the spring buds against frost, an important point in northern gardens, and is not unsightly. When the pushing buds are inconvenienced and no longer need it, remove the cover. Few who adopt this plan will regret it.—C. H.

A Charming Variegated Rose Border.

To increase the charm of beautiful coloured roses by contrast of other colours I planted borders of roses in two rows, giving a little more space between them than usual. Between the rose bushes I planted dwarf Delphinium chinense (Blue Butterfly) and blue gladioli in the following manner: every two spaces one delphinium alternating with one group of three gladioli. Especially good roses for this purpose are Sunstar, Mme. E. Herriot, Captain Ronald Clark, Hortulanus Budde, K. of K., Irish Fireflame, Isobel, Mrs. Haworth and Queen Alexandra. In early summer the cobalt blue delphinium blossoms form a very artistic contrast to the red shoots and leaves of the roses as well as to the colours of the flowers. The gladioli should be planted late that they may flower with the roses in autumn. Such borders are very harmonious and a striking feature for all visitors.—M. L. W.

An Easy Way to Increase Violas.

Those who are too busy to take viola cuttings will find the following an easy way of increasing violas: Mould up the centre of an old plant with a mixture of half leaf-mould and sand. In about a month most of the growths will have rooted in the compost. The whole plant can then be dug up and easily divided and replanted. Although September is the best month for this, it can be done from now until January, leaving the replanting until March.—R. M.

How to Make Lawn Sand.

Lawn sand is a mixture which is employed to assist the growth of grass on a lawn and at the same time to keep down weeds. The active ingredient of these sands is either sulphate of ammonia or sulphate of iron. Some "sands" contain as much as 30 per cent. of the former. Sulphate of iron mixtures are more useful for killing weeds and giving the grass a rich colour than for uses as a manure. These sands can be bought in prepared form with full directions for use. A good lawn sand can be made by mixing ½lb. of sulphate of iron (known as "copperas"), 1½lb. of sulphate of ammonia and 10lb. to 15lb. of any kind of sand. grind the chemicals into a fine powder and mix thoroughly. The cost of this quantity excluding the cost of the sand will be about 7½d., and it will prove a rich manurial substance which is able to kill daisies and other weeds. Spread it evenly over the lawn at the rate of 2 oz. to 4 oz. per square yard, or dust some into the heart of each weed to kill it.—G. ROBINSON.

Mealy Bug on Grapes.

The grower who has his vines infested with mealy bug during the summer and autumn months is greatly annoyed and troubled to see these pests getting into the bunches of grapes. As the berries begin to colour it is not safe to use the usual method of eradicating the pest and many bunches are spoilt by the time they are fit for the table. A method I have adopted with great success is to tie a piece of cotton wool loosely round the stem of each bunch of grapes. The mealy bug cannot get over or through the wool, which also acts as a trap. About once a week soak the cotton wool with methylated spirits, which will destroy all the bugs which have become entangled in the wool. The above procedure will help to tide over the trouble until the crop is cleared, when more drastic measures can be taken.—P. E. E.

Home-made Mats for Protecting Frames, etc.

These may easily be made by anyone having bracken or straw at hand and some stout string or cord. A handy size mat is 5ft. to 6ft. long and 2ft. to 2ft. 6ins. wide. To make this procure seven stakes 2ft. to 3ft. long and drive three of them into the ground about 10ins. apart and three more opposite them 6ft. away. One of these sets may be driven down till only 9ins. or so is left, but it will be found convenient if the other set is 18ins. or more out of the ground. Three lengths of cord are now required about 14ft. long. Attach one end of each piece of cord to each of the taller stakes, pass round the corresponding shorter stakes and fasten with a single knot, then back to the other end where all three cords are attached to the remaining stake, which acts as a handle to raise and lower the warp of the mat. The straw or bracken should be prepared in long thin bundles, then while one assistant alternately raises and lowers the handle above and below the standing cords, another assistant places the bundles of straw or bracken in between the cords. The mat should be "packed" occasionally so as to make it compact and even. When the warp is full the cords are untied from the stakes and corresponding ends securely fastened off.—W. M. W.

How to Preserve Runner and Kidney Beans for Winter Use.

I have for many years preserved runner and kidney beans in the following manner, and they come out fresh and are very much appreciated as a vegetable when others are scarce in the dead of winter. Get a large earthenware vessel and cover the bottom with about an inch of cooking salt, then lay a row of beans on the salt, cover up with salt, then another row of beans, and so on until you fill your vessel, covering the last row with about 2ins. of salt. Store in a cool, dry place. Before cooking the beans steep them about one hour, and this takes the salt out of them.—W. T. S.

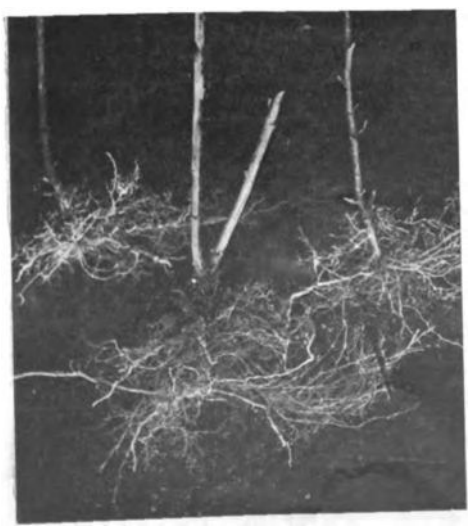
How to Grow Good Raspberries

THIS may appear to be quite a simple operation to many people. The raspberry is of so vigorous a nature that it rapidly recovers from the shock of ill-treatment. It is not like an apple or other fruit tree, or even a rose bush in this respect, for these will succumb even in the case of good treatment, so far as planting is concerned. The raspberry, then, is so accommodating that little trouble need be taken with planting? Oh, no! If this policy be followed—well, the raspberry will survive, grow, bear fruit; but compare the fruit with that of the properly planted, well grown canes, and the lesson it teaches will be startlingly obvious.

The point of that lesson is: If you want strong, thick canes, with a strong rooting system, that defies drought, bearing large, fleshy fruits in maximum quantities—give the best site and cultivation possible. If you are content with indifferent growth, the dying off of the canes just as the fruit begins to ripen, and the poor quality of the fruit that survives—just push the roots into the soil at any spot that may happen to be vacant or convenient and let nature do the rest.

There are undoubtedly thousands of canes planted under these latter conditions; whereas if only a little more attention and care were given there would be a vastly different result.

To obtain a good quantity of large fruits it is not necessary to plant a large number of canes. It is safe to say that if twenty-five canes were planted in the space usually given up to fifty, many more raspberries would be the result and the weight of the fruit doubled. We plant our raspberry canes too close to each other.



The raspberry possesses a mass of fibrous roots which call for special treatment and care.

The tips of the raspberry canes may be trimmed off just above the top horizontal wire used for training purposes.

In support of this I may mention that a certain part of my garden now used for vegetables, evidently used to be a raspberry plantation, for in two places raspberry shoots have appeared from pieces of root left there. These were left alone for the first year and the crops sown around them. The second year they bore fruit of a very large size. There is a row of raspberries of the same variety not far away from these individual plants, and from the latter two can be gathered more and finer berries each year than can be obtained from four or six in the orthodox row. This argues well for (1) a good site, (2) proper planting, (3) plenty of room, (4) good cultivation.

The raspberry cane possesses a large mass of fibrous roots, which occupy the top 6ins. of the soil, in addition to a few tap roots that go down deeper. It is the fibrous mass that matters to the cultivator, for on the healthy condition of these depends the production of fruit. In planting, these roots should be spread out in all directions; none must be doubled under, twisted, broken or bruised. It will pay to work some really good soil among these roots when planting, and planting must not be too deep—shallower in heavy soils than in those of a light nature. Plant firmly and with as much space as can be afforded between the plants. Just here are matters that should be considered. Once planted and established, it is unwise to interfere with the roots in the way of cultivating the soil; therefore, raspberries should have a site that is practically their own, and under such circumstances the rows, if more than one, may be closer together. It is a good plan to have two short rows rather than one long one, because a mulch can be placed between the rows, which will both benefit the roots and keep them well in that space, and help in preventing trespass upon the ground on the other side. The roots, being so near the surface, are very susceptible to feeding at all times—with artificial manures, rotted stable manure, liquid manure and a mulch of manure leaves and vegetable refuse in summer. The surface soil may be pricked up lightly with a fork, and the manures worked into the soil, but not so deeply as to disturb the roots.

Should the roots trespass and sucker canes are thrown up where they are not wanted, do not dig up the roots and tear them away, rather cut the roots through with a sharp spade or a knife.

The canes may be shortened a little after planting and as it is not advisable to allow fruiting to take place the first season, the canes should be cut down close to the ground in the spring—this will encourage strong, thick canes to shoot up, which will bear fruit well the next year. All thin shoots should be removed entirely at all times. As the fruiting canes progress in height they should be secured to horizontal strands of wire or to tall canes. Each autumn, every shoot that has borne fruit must be cut out close to the ground and the new canes trained in their place.—H. A. Day.

The cutting out of old wood close to the ground after fruiting is over.

LONICERA NITIDA . .

The New Hedge Plant.

THE GARDEN says:—
"Lonicera nitida supplies all the requirements for an evergreen hedge. It is completely hardy and of rapid growth."

This little known but extremely beautiful plant makes a dense hedge. The foliage is deep rich glossy green, with a bronzy tint in winter. It can be clipped to almost any dimensions and is not fastidious as to soil. We have a very fine stock of plants.

SPECIAL OFFER of FIRST-GRADE TREES and SHRUBS

LARGE ENOUGH FOR IMMEDIATE EFFECT

All wind resisters excepting the Acacias

SENT INEXPENSIVELY PER GOODS TRAIN AT LOWEST TREE-RATE

Packed Free for Cash with Order.

	Each
Acer Negundo, an elegant maple with pale green compound leaves, 8-12 ft.	3/6 and 6/6
Acer californicum, "The Californian Maple," very distinct and beautiful, 5-7ft.	3/6 ,, 4/6
Acer lætum rubrum, the young growths are beautifully tinted red: butter yellow in the autumn, 8-10ft.	5/6 ,, 7/6
Acer platanoides (Norway Maple), beautiful large green leaves, turning golden yellow in the autumn, 8-12ft.	3/6 ,, 5/6
Acer plat. Schwedleri, the purple leaf variety; beautiful coppery foliage, April to November, 8-12ft.	6/6 to 10/6
Acer pseudo-platanus, "The Sycamore," a grand "wind screen," 8-16ft.	4/6 and 7/6
Acer pseudo-plat. purpurascens, "Purple Leaf Sycamore," 8-12ft.	5/6 ,, 7/6
Alnus cordata, very rapid growing, excellent for marshy areas and poor chalky soils, 12-15ft.	5/6 ,, 7/6
Alnus incana, "The Grey Alder," do. do. 14-16ft.	5/6 ,, 7/6
Betula japonica, rare Japanese species, one of the most beautiful of all silver barked trees, 8-10ft.	5/6 ,, 7/6
Crataegus prunifolia, "American Thorn," superb for flower, berry and autumn colour, 6-8ft.	4/6 ,, 5/6
Fraxinus americana, the American "White Ash," a distinct and noble tree of fast growth, 4-5ft.	2/6 ,, 3/6
Fraxinus excelsior, "The Common Ash," excellent for wind-swept and coastal situations, 9-12ft.	3/6 to 6/6
Juglans regia, "Walnut," 9-12ft.	7/6 ,, 10/6
Ostrya carpinifolia, the striking "Hop Hornbeam," 8-10ft.	5/6 and 7/6
Pterocarya stenoptra, new fast growing Chinese tree, with wonderful foliage, 9ft.	5/6
Poplars in great variety, 9-16ft.	3/6 to 10/6

Write for our special offer per dozen, 100 and 1,000.

	Each
Robinia, in a variety of colours. (More commonly known as the "Acacia," one of the most elegant trees extant, 9-12ft.	5/6 and 7/6
Sophora japonica, the finest of the late autumn flowering trees, 8-10ft.	5/6 ,, 7/6
Ulmus, "Elms," in great variety, including americana, latifolia and nitens hybrids, 9-15ft.	4/6 to 7/6
A collection of one each of the above 20 trees, good specimens, for £5	

SPECIMEN FIRS, PINES, ETC.

	Each
Pinus Banksiana, the American "Jack Pine," grows in poor sandy soils, 3-5ft.	3/6 and 5/6
Pinus densiflora, the Japanese "Red Pine," 3½ft.	4/6
Pinus excelsa, "The Himalayan Blue Pine," 3ft.	5/6
Pinus Strobus, "The Weymouth Pine," 3ft.	3/6
Picea alba, "The Giant White Spruce," 3-4ft.	3/6 and 5/6
Picea asperata, heavy specimens of this rare Chinese species, 4-5ft.	10/6 to 21/-
Picea obovata, "The Siberian Spruce," 4-5ft.	5/6 and 7/6
Picea pungens glauca, the "Blue Colorado Spruce," 1½ft.	5/6
Abies nachalimensis, rare, 1½-2ft.	3/6 ,, 5/6
Abies numidica, rare, 3ft.	7/6
Abies concolor violacea, beautiful deepest blue foliage, 2ft.	7/6
Tsuga canadensis, the elegant "Canadian Hemlock Spruce," 3-4ft.	5/6

One each of the above 12 Conifers for 60/-

12 Flowering Shrubs (Deciduous and Evergreen), in 12 varieties, 2-5ft. dos., 12/-; 100, 125/-

12 ,, ,, ,, ,, Choice newer varieties, 3-5ft. dos., 30/-; 100, 250/-

All to name, distinctly labelled, in beautiful variety, our selection of sorts.

BEHIND THE SCENES

The Last Clearing up of Garden Rubbish.

THERE is no season in the year when the accumulation of garden rubbish is so great as in the late fall. Of course, the foliage from most deciduous trees, and especially that of the oak, elm, beech and lime, will, in course of time, form excellent leaf-mould, which will be of great value to the gardener. Foliage of this kind should be stacked in a mass, which is turned occasionally so that the rain may get at all parts and hasten decomposition. Much of the garden rubbish will have to be destroyed, and this includes leaves from evergreens (these do not make good leaf-mould), weeds, and practically all the waste material from the flower and vegetable garden. Any refuse from the vegetable plot should certainly be burned without delay, as this is extremely likely to harbour pests of one kind or another.

In the burning up of garden rubbish the gardener is confronted with rather a difficult problem. Whatever the nature of the material may be, the slower the process of combustion the better, if one is simply considering the value of the resulting ashes. With a slow fire more carbon or charcoal is preserved in the refuse, and this is a valuable constituent in the ashes. Thus, if the fire can be arranged in some out-of-the-way corner where it will not annoy anyone with its smoke, a quick fire is undesirable. Get a good body of fire going with sticks and dry material, and then add the garden rubbish. Such a fire will continue smouldering (and smoking) for many hours, or even days, and in the end ashes rich in valuable plant foods are secured. This is the ideal method of dealing with garden refuse, but it is one which is difficult to carry out in the neighbourhood of towns.

MAKING THE FIRE.

Where the amount of refuse is comparatively small, the following is a good plan to adopt. Get three or four empty fruit cans or any smaller kinds of tin. With a tin-opener, work out a number of holes all over the cans, making these of a good size. Now arrange the cans (inverted) on the site where it is proposed to have the fire. Over the cans scatter a thickish layer of paper or any dry material. A few pieces of wood on the top will help to establish a better fire. Set the mass alight and, when it is burning strongly, place the refuse lightly on the flaming area. Do not put too much at the start, but feed the fire every now and then with the rubbish. The perforated cans at the base ensure a free passage of air which keeps the fire burning briskly, and it is amazing how easy it is to burn up even green refuse in this way. Where a large amount of rubbish must be dealt with it is better to form a special incinerator. Bricks can be laid in four layers in the form of a square; the bricks are placed so that there are ample openings for the admission of air on all sides. With this device a very large amount of garden refuse of all kinds may be burned up in a remarkably short time and, if the fire is kept going brightly, without a considerable amount of smoke. It is, of course, easy when, for any reason, the fire becomes dead, to push sticks or any dry material into the openings between the bricks. In some cases it is undoubtedly worth while to purchase one of the special incinerators for garden refuse which are now on the market. These enable one to destroy garden refuse with a minimum of trouble and annoyance.

In whatever manner the refuse is burned up, try to make one job of it if possible. Smoke from garden bonfires is decidedly unpleasant, especially when this finds its way into houses. Never start a garden fire on a very windy day, for then much of the burning stuff will blow about. Tend the fire right up to the end, until everything is reduced to ashes, as it is annoying to have to deal with a quantity of half burned material.

A FIRE MAKES A FERTILISER.

As has been indicated, by the burning of garden refuse one not only destroys a lot of rubbish, but, at the same time, a valuable fertiliser is secured. Bonfires in the garden should always be set going in dry weather, not only because they burn better, but on account of the fact that it is a mistake to let the ashes get wet. Potash is the chief fertilising property contained in the ashes that come after the burning of waste sticks, prunings, weeds, etc. If the ashes are exposed, the potash is largely washed out and the value for fertilising purposes is lost to a considerable extent. When the fire has burned out and the ashes have cooled, they should be collected and stored in a dry place until required for use. Fruits and vegetables appreciate the ashes derived from burning garden refuse, and the material is also valuable for mixing with potting soil. Always the addition of vegetable ashes will prove very helpful to a strawberry bed. In the kitchen garden the ashes may be employed in connection with onions, carrots, beet and potatoes. Work the ashes lightly into the soil and the first heavy shower of rain will ensure that the potash they contain is carried downwards. Lawns that are thin or patchy may also be treated to a dressing of the ashes, and often the result is surprisingly good.—LEONARD BASTIN.

THIS MONTH'S COMPETITION

THIS month's competition is one that should appeal to all gardeners. Which are the Six Best Michaelmas Daisies? Each gardener will have his own ideas on the subject. The point is, which are the six Michaelmas daisies that will get the greatest number of votes. The result will not only be interesting but will help all readers to make their choice for this season's planting.

LIST OF PRIZES.

FIRST.—Three of each of the six best Michaelmas daisies as voted by readers of THE GARDEN.

SECOND.—Two of each of the six best Michaelmas daisies.

THIRD.—One of each of the six best Michaelmas daisies.

In the case of ties the prizes will be divided.

RULES.

1.—A list of your choice of the six best Michaelmas daisies to be sent in in order of preference on the coupon to be found on page iv. of this week's issue of THE GARDEN. A coupon will also be found in next week's issue.

2.—No reader may win more than one prize, but they may send in any number of lists, provided that they are written on the special coupon to be found in this and the next issue.

3.—Coupons must reach this office not later than Wednesday, November 17th.

4.—Envelopes must be marked "Competition."

5.—The popular vote will be final and no correspondcene will be entered into over this competition.

6.—The result will be announced in the issue of THE GARDEN, December 4th.

7.—The Editor's decision on all points is final.

Matting for Frames.

IN time of frost the protection of frames is indispensable, and even hot-beds are all the better for some covering. Many gardeners do not realise the extent to which even a few hours of frost will damage or retard tender plants. On this account a supply of mats for spreading over the frames should always be at hand. For the purpose the well known Archangel mats, made from the soft, tough inner bark of the common lime tree, are probably the best. These mats are often sold in two qualities, heavy and light, and usually measure about 7ft. by 3½ft. Often the Archangel mats are received in rather a rough state, though they are none the worse for that if they are given a little preparation before use. The rough pieces of bark round the edges should be pulled away and the ends of the strands tied three and four together. This will very much lengthen the life of the mats, which will otherwise wear badly from the edges. Somewhat more expensive than the Archangel mats are those made of Welsh grass. These are very durable, and probably, in the long run, they are worth the extra money. Quite serviceable mats for frames can be made at home on a frame from straw.

PROTECTION BY DAY.

Of course, it is only in very keen weather that frames will be required to be protected by day as well as by night. Usually the mats will only be placed on the frames at sundown when there is a risk of frost, and these should be removed as the temperature rises in the morning. It is a great mistake to throw the mats in a heap, as is sometimes done. Quite likely they are thoroughly damp through the melting of the hoar frost which they have collected. Mats should always be hung up on a wall or a fence so as to dry them as much as possible. A thoroughly wet mat over a frame will have a terribly chilling effect and, in severe frost, will be of no value at all as a protection.

Keep the Sticks and Stakes.

BEAN poles and pea sticks, as well as any stakes used in the flower garden, should be stacked on one side for examination. Of course, those that are broken will not be of much use, and these can be added to the fire. In the case of all the sound ones, clean away any soil from the base and then leave in the open on a fine day, so that they may become quite dry. Then sort them carefully into the different sorts and sizes, and tie up into bundles. Store in a shed where the rain cannot get at them. It is a great mistake to leave bundles of sticks and stakes out of doors all the winter, as many of them are sure to rot. The gardener will find it really worth while taking care of these accessories in the garden and so avoiding the expense of having to buy a fresh lot next season.—B. W

OUR SERVICE BUREAU

Though so many subjects are dealt with in each issue of THE GARDEN, *it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, there is always information available from a staff of expert contributors and consultants; and there is no charge for this. It is one of the additional means of service which* THE GARDEN *is glad to render to its readers.*

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope and the coupon, that will always be found in each issue, shall be sent with the enquiry. We would point out, however, that we cannot undertake to supply readers with plans and designs of gardens, but will willingly assist in giving suggestions for planting.

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2.*

We have selected the following enquiries, with their answers, as being of more general interest, and therefore worthy of publication.

Roses that have Failed.

Can you advise me about roses. My beds are cut out of gravel, 3ft. deep and filled in with manure and soil (loamy clay) in alternate bands. This was first done five years ago. The first three years the blooms were exquisite and three good crops each year were obtained. After each blooming period rose fertiliser was added. Pruning was done twice per year and in cutting blooms they are taken with a good stalk and cut. Last year some of the beds which had all sunk below the level of the lawn were added to, the trees being taken out and replanted. My present trouble is that few of the roses show any growth, many have died, many are most unhealthy, with no leaves, and this pertains even in replacements.
The varieties are (bed of each):
Mrs. Henry Morse.—No deaths, fairly good, bloomed well, bed made up last autumn.
Christine.—Also made up, fairly good show, but no growth now and unhealthy.
Golden Emblem.—Very poor, no growth and few blooms, bed made up.
Los Angeles.—Nearly all dead, including replacements, bed raised.
Col. Oswald Fitzgerald.—Poor as Golden Emblem.
Queen Alexandra.—As Golden Emblem, bed not touched.
Red Letter Day.—Fair, but not so healthy as before.
Irish Singles.—Four varieties in very large bed, poor, no growth.
Madame Butterfly and Ophelia.—Bed not touched, bloomed very well, but no growth.
Miss Van Rossen.—Unhealthy, bed not touched.
In seeking for the cause I am reminded that last year we put sewage water pumped from cesspool. Is it possible that has affected all the beds, as you will see some have been made up and some not, and yet all have suffered more or less. As a contrast, some odd standards pushed into the gravel with no care have been exquisite. It is not mildew or fly. Kept syringed and spring growth this year was fresh and good. Could I have your kind advice?—V. T., Much Hadham, Herts.

Judging from your very clear description of the rose beds and their treatment, it is most likely the sewage water that has destroyed the roots, especially if the sewage was not well diluted with clear water, and then applied immediately after a watering of the soil with clear water. In the circumstances we advise you to lift and replant the roses this autumn, adding some fresh soil to each bed. The varieties are choice ones and deserve the trouble being taken with them.

Replanting Rose Beds.

I desire to replant my rose beds. Would you recommend when the bushes are lifted, just forking the soil over and replanting or would you let it settle down for, say, a fortnight, heeling the bushes in, and then replanting. The soil is a particularly heavy clay and quite unmanageable when the rains come, and there would be a risk in the latter method (which on lighter soils, I think, would be the better one). As I am introducing a few new plants, I presume it would be best to incorporate some lime with the soil to sweeten it for their reception. I find that new plants introduced among old ones invariably do not do well on account of the soil being too rich for a start.—J. L., Shipston-on-Stour, Worcs.

It is certainly advisable to let the soil in your rose beds settle down before replanting. We should advise you to dig it over now, and order your roses in a fortnight or three week's time. If you put in lime, it must be very old, and the more lime you add, of course, the longer your ground will have to remain fallow before you plant the roses. If you could get a little old mortar rubble and dig it well in, it will certainly help to break up your clay.

Climbing Roses for Pillars.

Will you please advise me by giving names of some climbing roses suitable for pillars, 6ft. to 8ft. in height, hybrid teas preferred. Would any of the following be suitable? Climbing General McArthur, Liberty, Richmond, Lady Hillingdon, Mme. Mélanie Soupert, W. A. Richardson, Caroline Testout, Colcestria, Lady Ashtown.—C. C., Dereham, Norfolk.

The climbing forms of most roses may be relied upon to furnish pillars 6ft. to 8ft. in height. The following hybrid tea varieties are to be especially recommended. Florence H. Veitch, bright crimson; Grüss an Teplitz, crimson, very free flowering; Lady Waterlow, pale salmon blush; Sarah Bernhardt, shades of scarlet and crimson; J. B. Clark, scarlet crimson, with dark flushing and Climbing Paul Lede, yellow and rose. From your list we should prefer Climbing Liberty, Climbing Lady Hillingdon, Climbing Caroline Testout and Climbing Lady Ashtown.

When to Apply Manure and Lime.

I want to put stable manure and lime in my garden, but I have been told that a few weeks should elapse between both, that is if I put the stable manure first. My garden was meadow-grass until last year and the soil is clay. I should be very much obliged if you will kindly tell me what is the right thing to do.—H. F., Wembley Park.

It is, on the whole, better to apply the farmyard manure and the lime at separate intervals. The stable manure should be put in first, and after an interval of two or three weeks the ground should be dressed with lime, not necessarily dug in, but left scattered over the surface of the ground, and with the gradual weathering, due to wind and rain, the lime will soak into the soil. The ground should be left to lie fallow for the winter.

A Climbing Rose for a Wall.

I require a climbing rose for a house wall (concrete) facing practically due west. Can you recommend a hardy type which will bloom over a long period of the year, and will it be necessary to trellis the wall?—H. P., Leeds.

We should suggest that you plant Rose William Allen Richardson against the west wall of your house. This deep orange-yellow rose produces its flowers for many weeks and is a vigorous grower. It would be advisable to put up some form of trellis, either wire or square oak. This should be placed close to the wall, and the rose growths trained neatly to it. The roses would grow more satisfactorily against the trellis than against concrete, and it is far easier and quicker to train the trees if trellis is used.

Evergreen for a Screen.

Will you kindly recommend an evergreen flowering bushy shrub, with berries in autumn, suitable to plant as a screen (not a hedge) for south-east Scotland in a south exposure? It would require to grow about 5ft. or 6ft. high. Would Pyracantha coccinea be suitable, and what kind of flower has it?—M. Y., Melrose.

We should suggest that you plant Berberis stenophylla for the purpose of the screen you have in view. It is very bushy, reaching 7ft. or 8ft. in height, and is very decorative with its long arching branches, which in spring are a mass of golden yellow flowers and in autumn are covered with bright red berries. Pyracantha coccinea would also prove quite effective, but it is really more suitable as a wall plant.

Root Mediums for Gentians.

Would you please supply me with particulars of how to make a good gentian bed? Peat is not obtainable in this neighbourhood, but I have a quantity of leaf-mould. The sand in this district contains a high percentage of lime. I should like to grow most of the well-known gentians, e.g., GG. sino-ornata, Farreri, acaulis, Purdomi, etc., and shall be greatly obliged if you will supply me with particulars.—D. P., Cornwall.

There is really no need to go to the trouble of preparing special beds for your gentians. This was thought necessary in the past when little was known about the cultivation of different species. On the whole the beds should be made early in the year. Gentiana sino-ornata does well in a bed of a mixture of peat, sand and leaf-soil which should go down to a depth of one to 1ft. in order to give the roots a moist root-run. It might be advisable to incorporate a little manure with the soil, as this gives an additional holding capacity, which is useful in the summer for retaining moisture which is so necessary for the gentians. Gentiana verna requires a little different treatment. Where this species is to be grown, the soil should be dug out to a depth of about 2ft., placing rough stone at the bottom, and filling with loam, leaf-soil, some moss peat and mortar rubble. Gentiana bavarica does well in a sandy compost which is kept fairly moist. G. Farreri is a very difficult to establish in some gardens. The ground should be prepared and dug out to a depth of 2½ft. and filled with loam, leaf-soil and a little peat, supplying at the same time good drainage in the form of loose stones. GG. acaulis and septemfida do well with fairly ordinary treatment such as a mixture of loam, leaf-soil and little peat.

BEAUTIFUL BERBERIS

No other hardy shrub has quite the same attraction in Summer, Autumn, Winter and Spring as the many lovely varieties of Berberis, the following are a few of the most attractive.

Lincinna	..	1/6 each; 15/- dozen.
Darwinii	..	2/- each; 24/- dozen.
Darwinii	..	2/- each; 21/- dozen.
Polyantha	..	1/6 each; 15/- dozen.
Prattii	..	1/6 and 2/6 each.
Pruinosa	..	1/6 and 2/6 each.
Saphiana	..	1/6 each; 15/- dozen.
Stenophylla	..	2/- each; 24/- dozen.
Thunbergii	..	1/6 each.
Prescens	..	1/6 each.
Wilsonii	..	1/6 each; 18/- dozen.

For other varieties see our Tree Catalogue posted free on application.

PUBLICATIONS RECEIVED.

"Winter Blossoms from the Outdoor Garden," by A. W. Darnell. (L. Reeve and Co., Limited, 21s.). Gardening books which collate and collect scattered information are always valuable, since they present in limited space a ready reference, useful for amateur and professional gardeners alike. The present work is one of such a kind, and forms a valuable addition to horticultural literature.

It is a volume of a unique kind, in so far as it describes over 350 species of plants, exclusive of hybrids and varieties, which blossom during the winter months in gardens in the British Isles. Nearly all the plants described are hardy, a few requiring shelter in exposed and northern situations. It is more than usually interesting since the subject of winter flowers is one which has become of late years of increasing importance, and it is the ultimate aim of the majority of gardeners to have bloom in winter as well as during the more hospitable seasons of the year.

The information contained in the pages is most certainly up to date and the number of species described which are only of comparatively recent introduction, shows the author's intimate knowledge of what is happening in the horticultural world. All kinds of plants are included: shrubs, trees, rock and alpine plants, bulbous plants and irises, and so on. The descriptions are written in a simple and lucid way, all technical terms, which generally harass the amateur, being omitted or simplified. With the simplification, however, there has been no loss of accuracy. In addition to these descriptions, details are given of the plants in their native habitats and cultural directions are given in every case for the raising and growing of the plants in one's own garden. Altogether it is a most interesting and helpful book, supplying a vast amount of information in a limited and convenient space, admirably arranged, on a subject which all true gardeners have close at heart.

All amateurs will find the illustrated preface on "Plant Propagation" of great assistance when they come to the raising of their own stock of plants. It is an aspect of gardening which is rather scantily dealt with in most other books and for that reason it is more than usually welcome in this one.

The line illustrations, also done by the author, are exceedingly well executed, as are several of the coloured reproductions, while the book is well printed. One or two errors occur in plant nomenclature, but on the whole the book is remarkably free from blemish.

"The Cultivation of Citrus Fruits," by H. Harold Hume. (Macmillan and Co., 21s. net.) A comprehensive treatise on the growing and cultivation of citrus trees.

"Modern Gardens," British and Foreign, with a Commentary by Mr. P. S. Cane. (The *Studio*, price 7s. 6d. net.)—A collection of illustrations of gardens throughout the world, showing the different types of garden design peculiar to the country. In the preface Mr. Cane gives a history of gardens pertaining to these different countries, with notes on the selection of sites for a garden and its planning and planting.

"A Simple Guide to Rock Gardening," by Sir James L. Cotter. (The Sheldon Press, price 2s. 6d.)—An admirable little book for the amateur gardener who wishes to take up rock gardening. Many useful hints are given on the cultivation and treatment of rock plants, and a number of lists of plants suitable for different positions in the rock garden are given which should prove most serviceable to those who find the selection of rock plants for various positions somewhat difficulty. All kinds of plants are dealt with—alpines, bulbs, irises, shrubs, orchids and so on—so that the amateur will find all his needs catered for in the compass of this small book.

WAKELEY'S *Celebrated* Hop Manure

(PATENTED)

THE ORIGINAL AND ONLY RELIABLE SUBSTITUTE FOR STABLE MANURE

AS USED IN THE GARDENS OF GREAT BRITAIN

DIPLOMA AND MEDAL, ROYAL INTERNATIONAL HORTICULTURAL EXHIBITION, 1912

DO YOU REALISE IT?

A large bag of WAKELEY'S PATENTED HOP MANURE at a cost of only 7/- carriage paid to your door (if within 25 miles radius of London, or at a trifling extra if beyond), GOES AS FAR AS A CART-LOAD OF STABLE MANURE, without any of the defects of the latter; gives better results, is easy and clean to use.

Every ounce of Wakeley's Hop Manure is of value to the soil, supplying the necessary HUMUS in addition to the valuable plant food. Worthless rubbish is not added to make weight (as is the case of some artificial manures advertised).

Thousands do realise it, the proof of this is the constant flow of UNSOLICITED LETTERS received from time to time in praise of the wonderful results obtained at such a moderate cost (see Booklet for selection).

BEWARE OF IMITATIONS.—Genuine Only in our Marked Bags containing Guaranteed Analysis.

ILLUSTRATED CATALOGUE giving full particulars and testimonials sent on receipt of postcard.

CASH PRICES (including bags):

Small (about 1 bushel)	3/-
Large (about 4 bushels)	7/-
5 Large	33/9
10 Large	65/-
20 Large	120-

Carriage paid by Pickford's or to any station within 25 miles of London, including delivery if within free delivery radius of Railway Company; 6d. per bag extra for every 50 miles or part beyond. Maximum extra charge Great Britain, 2/6 per bag.

WAKELEY BROS. & CO., LTD.

75a, BANKSIDE, LONDON, S.E.1

"Auto-Shreds" did it!

I just burnt them on the ground and they thoroughly fumigated my plants. The judge wanted the name of the stuff that kept my flowers so insect-free. I told him "Darlington's AUTO-SHREDS." At all seedsmen they cost

No. 1. (To fumigate 10,000 cubic feet.) For tender or ordinary plants. 6/-

No. 2. 10,000 c.f.) Ordinary plants 4/6

No. 3. (1,000 c.f.) Ordinary or tender plants ... 1/-

No. 4. (2,500 c.f.) do. 1/9

NEW HARDY CRIMSON BROOM

AT Chelsea Show (1925) the King said "That red Broom is certainly very striking." This was the new crimson Broom "Dorothy Walpole," which received the unanimous Award of Merit from the R.H.S. as well as other distinctions in London and on the Continent. Plants have been sent to U.S.A., Canada, Australia, New Zealand, France, Holland, etc.

In the Field, *a well known ex-Curator of Kew Gardens wrote: "The richest coloured Broom known is one named 'Dorothy Walpole.' It is as hardy as the common Broom . . . and is very free-flowering . . . the colour is rich velvety crimson . . . more attractive than any of the coloured Brooms yet seen." The colour far surpasses Cytisus Dallimorei, and the growth is as vigorous as C. Andreanus; it requires no special treatment nor any kind of protection whatever—just a hardy shrub for ordinary garden soil in any part of the British Isles, however far north.*

A Vice-Chairman, Floral Committee, R.H.S., wrote: "Everyone who has seen my plant has been astonished at its warm glowing red"; and from a lady in Devon: "I am so delighted with the Broom 'Dorothy Walpole.' It has done splendidly and is like a sparkling gem in the garden—one mass of flower."

NEW SEASON'S PRICES.

Strong pot-grown plants now ready for planting out, to flower in May, 7/6 each. Carriage paid rates to any station in Great Britain or Ireland: One plant, carriage paid, 10/-; two plants, carriage paid, 18/6; three plants, carriage paid, 26/-; six plants, carriage paid, 49/6; twelve plants, carriage paid, 99/-.

Coloured illustration sent on application if THE GARDEN *is mentioned.*

KNAP HILL NURSERY
WOKING, SURREY
(*Late Anthony Waterer*)

The Executors of the late
HOSEA WATERER
have pleasure in offering

STANDARD TREES

in great variety, consisting of

LIMES, NORWAY MAPLES, ELMS, etc., etc.
EVERGREEN & DECIDUOUS SHRUBS, viz.:

Box—Green and Variegated, 3 to 8 ft.
Hollies—Common, 5 to 8 ft.; Variegated and Green varieties, 2 to 6 ft.
Thuiopsis borealis, 10 to 12 ft. Cupressus Lawsoniana, 12 to 14 ft. Cedrus atlantica glauca, very fine, 14 to 16 ft. Osmanthus, Phillyreas, Spireas, Lilacs, Viburnums, etc.

GOLDEN YEWS
A Magnificent Stock in all shapes and sizes from 2 to 10 ft.

PRIVET, Common and Oval-leaved.
QUICK and **HORNBEAM** for Hedges.
AZALEAS, in great variety, 2 to 5 ft.
RHODODENDRONS, without doubt the finest stock in the trade of named varieties, 2 to 6 and 8 ft.
HARDY HEATHS in great variety and a good general nursery stock.
Catalogues ready.

Enquiries and Inspection invited.

Allens ROSES

To-Day's Opportunity Ensures Next Summer's Delight

The present time is ideal for planting roses. The following selections are comprised of tip-top quality plants at a moderate price.

DO NOT DELAY—
STOCKS ARE NOT HEAVY

Our **"Supreme" Collection** of 12 Dwarf Roses in first-rate varieties, carriage paid, for **13/6** cash with order.

Betty Uprichard, coppery salmon.
Hortulanus Budde, vermilion scarlet.
Admiration, cream washed vermilion.
Elsie Beckwith, rose pink.
Huguette Vincent, cerise pink.
Lady Pirrie, coppery salmon.
Lord Charlemont, deep crimson.
Lamia, orange.
Mabel Morse, the grand new golden yellow.
Florence L. Izzard, pure buttercup yellow.
Sensation, rich velvety crimson.
Souv. de Georges Pernet, coppery pink.

No rubbish. All first quality maidens on Briar Stocks.

Our **"Standard" Collection,** any 3 of the following selected Standards, **10/-** carriage paid; any 6, **19/-**; any 12, **36/-**

Betty Uprichard, coppery salmon.
Los Angeles, coral rose.
Mme. Edouard Herriot ("Daily Mail" rose).
John Russell, new, deep crimson overlaid black.
The General, crimson, an advance on Hugh Dickson.
Mrs. C. V. Haworth, cinnamon cerise.
Elizabeth Didden, rose pink.
Crimson Columbia, a crimson form of Columbia.
Sensation, rich velvety crimson.
Mrs. Beckwith, lemon yellow, fine form.
Elsie Beckwith, rose pink.
Lord Charlemont, deep crimson.
Snow Queen, the indispensable white for standards.

WEEPING STANDARDS, in extra fine quality trees, 5-6ft. in height, price **6/-** each, carriage paid: **Fernand Rabier, White Dorothy, Yvonne, Havering Rambler, Papa Gouchault, Sodenia, Hiawatha, Leontine Gervaise, Chatillon Rambler.**

"Pet" Collection of Polyantha Roses. 12 fine varieties, including our novelty **Rufus,** the finest scarlet rose in this section, carriage paid, **12/-,** cash with order.

Alice Amos, cherry pink, white eye.
Diana, orange tipped carmine.
Dorothy Howarth, coral rose pink.
Ebloulssante, velvety crimson.
Ideal, dark scarlet.
La Reine Elizabeth, dark red.
Lady Reading, rosy pink.
Leonie Lamesch, coppery red.
Orange King, new deep orange.
Rochette, cherry red.
Tip Top, delightful double blooms, yellow tipped rose.
Rufus, the finest scarlet, unaffected by weather.

BUY FROM THE GROWERS, ALL GUARANTEED first quality plants from our Norfolk rose grounds.

Nurserymen, NORWICH, NORFOLK
Established 1869.

Notes from Maidstone.

MYROBALANS and MIRABELLES.

These two plums are often confused. The Myrobalan (Prunus cerasifera) when first introduced into Europe was thought to be the souce of the dried fruits known as Myrobalans, so largely imported into Europe in the Middle Ages for medicinal uses, hence the name was applied quite wrongly to the plum. There is no better fruit for bottling, and we offer the Red and Yellow varieties, extra stout Standards, at 7/6 each.

The Mirabelle is a miniature gage of delicious flavour and making an unequalled preserve, Half-Standards at 7/6 each.

George Bunyard & Co., Ltd., The Royal Nurseries, Established 1796. Maidstone.

TITTENHURST
Rhododendron

JOHN WATERER, SONS & CRISP, LTD. beg to announce that in this fine collection they still have for disposal examples of the best hybrids raised at Tittenhurst, Sunningdale, which are priced as follows:

Doncaster × **Aucklandii roseum superbum** each 3ft. to 6ft., from **63/-** to **105/-**
White Pearl × **Aucklandii roseum superbum** 2½ft. to 4ft., from **42/-** to **63/-**
H. M. Arderne × **Aucklandii roseum superbum** 3ft. to 4ft., at **42/-**
Cynthia × **Aucklandii roseum superbum** .. .. 3ft. to 4ft., at **42/-**
Luscombeanum × **Ivoryanum** 3ft. to 4ft., at **42/-**
Mrs. Thistleton Dyer × **Standishii** 2ft. to 3½ft., from **21/-** to **42/-**
Helen Schiffner × **Mrs. Charles Butler** 3½ft. to 4½ft., at **42/-**
Other fine crosses, from **7/6** to **21/-**

A number of fine specimen plants of **kewense** and **Gill's Hybrids,** from **63/-** upwards.

THE GARDEN

VOL. XC.—No. 2867. NOVEMBER 13, 1926. PRICE TWOPENCE.

NOTES OF THE WEEK.

THIS MONTH'S COMPETITION

LIST OF PRIZES.

FIRST.—Three of each of the six best Michaelmas daisies as voted by readers of THE GARDEN.

SECOND.—Two of each of the six best Michaelmas daisies.

THIRD.—One of each of the six best Michaelmas daisies.

In the case of ties the prizes will be divided.

RULES.

1.—A list of your choice of the six best Michaelmas daisies to be sent in in order of preference on the coupon to be found on page x. of this week's issue of THE GARDEN. A coupon will also be found in last week's issue.

2.—No reader may win more than one prize, but they may send in any number of lists, provided that they are written on the special coupon to be found in this and the last issues.

3.—Coupons must reach this office not later than Wednesday, November 17th.

4.—Envelopes must be marked "Competition."

5.—The popular vote will be final and no correspondence will be entered into over this competition.

6.—The result will be announced in the issue of THE GARDEN, December 4th.

7.—The Editor's decision on all points is final.

The Importance of Labelling.

LABELLING is one of the problems of the garden. It is also a subject on which many gardeners hold strong views. On the one side are those who consider labels as the ugliest of all things in the garden; on the other are those, many of them specialists, who believe that everything should be labelled. The truth is that labelling is most important up to a point, but that there is a happy mean that should be aimed at.

If a garden notebook is kept, there is little need to label vegetables, annuals and other short-lived plants, provided that the number of varieties grown of one plant is not large. On the other hand, wooden labels are usually used in the seed boxes and it is little trouble to remove them when the plants are set in their final positions. More important are the more uncommon alpines and herbaceous plants, for many of these have long names that are difficult to memorise. Also, you must remember that the less common the plant the more will you be asked its name. Fruit and trees and shrubs are the most important of all, for these live long, and everyone knows by experience how difficult it is to remember varieties. You may wish to order fresh supplies, or a neighbour may admire something that you possess. How frequently does it happen that you are unable to tell him the name and then you have to take the trouble to send away a specimen for the correct name. Some nurserymen recognise the importance of correct labelling and send a permanent label with the plants; many more do not. But we should like to impress on all our readers that correct and permanent labelling pays.

That gardeners are beginning to realise its importance is proved by the numbers of various classes of labels that are now on the market. For seed pans or short-lived plants there is nothing to beat the ordinary wooden tally, or, still better, the celluloid tally, that can be used over and over again. More permanent labels are those made of pottery, on which you write with indelible ink, and very excellent and inoffensive they are, particularly in the rock garden, and the old-fashioned zinc label, which has the disadvantage of oxidising and becoming almost unreadable in time. The most expensive and the most permanent are cast metal labels and a most excellent kind where the lettering is fired on to white, buff or green porcelain. Either of these kinds will stand up against all weathers for many years, and in the case of permanent plants are the cheapest in the long run.

HAVE YOU

¶ *Examined your bulbs which are now standing in pots covered with ashes? Those which have made about 2ins. of growth should be removed to a cold frame.*

¶ *Finished the lifting of your dahlias and planted your bulbs?*

¶ *Examined the fruit in your store room and removed any specimens showing signs of decay?*

¶ *Given your fruit trees a dressing of basic slag at the rate of 4oz. per square yard?*

¶ *Added more grease to the grease-bands on your fruit trees?*

¶ *Dusted with flowers of sulphur any plants in the cold greenhouse which are attached with mildew? All diseased leaves should be removed and the atmosphere should be kept as dry as possible?*

¶ *Inserted cuttings of gooseberries and currants?*

The Flame Flower: Tropæolum speciosum.

THIS magnificent climber is a native of Chile and like so many Chilean plants it grows particularly well in Scotland. Gardeners in the south sometimes find it difficult to manage, though on the other hand one may occasionally see it in English gardens flourishing quite as well as ever it does north of the Tweed. The root of the flame flower is long and white and fleshy, rather like the root of the bellbind. It goes questing about just below ground and throws up its slender climbing shoots wherever it can find a bush or hedge to support it. The plant can be grown up a wall or a fence if given strings, wire or some such support to cling to. Let it find its own way up. Never attempt to "train" it. Existing wall climbers, such as cotoneaster or ceanothus, make an ideal support. Never does Tropæolum speciosum look so effective as when rambling over a yew hedge, the rigid lines and sombre colour of which make a splendid foil to the lightness and brilliance of the flame flower. The climbing growths of flame flower may usually be regarded as annual, though the roots are perennial, but we have known the top growth to endure a mild winter and start off into fresh growth in spring from where they left off the previous autumn. Not content with its glory of apple-green and flaming scarlet, T. speciosum produces seeds of exquisite beauty. These are about as large as peas and of a wonderful turquoise blue. They hang in twos and threes exposed in the bursting capsules. The chief points to remember are that it prefers some living host on which to ramble, that it likes its roots cool in the shade of its host and its branches trailing out into the light and air. It may be planted in autumn or spring.

PLANTS THAT SHOULD NOT BE NEGLECTED

Gardeners are always glad to receive information about plants that have been particularly noted in other gardens. Week by week plants that are really worth growing are described in this page.

Trollius Orange Globe.

THIS is but one of the globe flowers which are very serviceable and free-flowering at that early period of summer when there is so often a gap or break between the real spring flowers and summer's multitude, but Orange Globe is decidedly one of the varieties which should not be lightly passed by, whether one aspires to possession of a representative collection or has room only for a few plants and wants these to be extra good. The illustration suffices to show how uncommonly effective the flowers and foliage of this trollius are, and its colour is as brilliant as real orange can be. The one thing these plants enjoy, and must have in order to do thoroughly well, is a good depth of well worked soil, and so long as it is well worked it is all the better for being strong and heavy. If the soil is light and dry a liberal addition of spongy, moisture-holding material will be of great advantage. Peat is useful, but all things considered I am disposed to think a fairly liberal dressing of hop manure is more beneficial to trollius than anything. The hops supply the loose, fibrous humus-forming substance to which the roots can cling, and the chemical treatment to which Wakeley's Hop Manure is subjected, gives just the additional tonic and nourishment that plants of the character of trollius require. It is not too late to plant trollius now for next season's display, if good, well rooted clumps are planted and the crowns can be just covered with loose, dry leaves. The best time to divide old clumps for increase of stock is as soon as the flowers have faded.

Other varieties which will prove highly decorative and useful are TT. Gold Cup, Ledebouri, Canary Bird and giganteus.—A. J. M.

The Dalmatian Toadflax.

A GOOD border linaria, L. dalmatica, deserves to be better known. It is offered by most hardy plant dealers, either in the typical variety or the finer L. dalmatica macedonica. It grows about 2½ft. in height, and has erect spikes of large yellow flowers, touched with orange. It is not difficult to grow in ordinary soil, and, although it runs slightly, is not unduly aggressive. A variety, called L. macedonica Nymph, has cream-coloured flowers, but I do not consider this any gain, although some appreciate it highly. L. dalmatica may be increased by seeds or division. It likes a sunny place in the border, when it will flower well.

A Useful Prostrate Shrub.

THIS shrub (Cotoneaster humifusa) was introduced by Wilson from China in 1900, and subsequently by Farrer if not others, as C. Dammeri radicans. It is a most ornamental and useful little shrub. Being perfectly prostrate its network of slender branches and willow-like, evergreen leaves make an admirable covering for the face of a sloping rock or bank, but it will also prove a first-rate carpeter on the flat, either in the open or beneath woodland trees and shrubs. The white flowers, which are ¼in. wide and held on upright stalks, are followed by coral-red fruits which look like so many holly berries scattered about the ground. At the same time the older of the dark green, glossy leaves assume bright tints of orange, so that the effect is one that blends very delightfully with the hues of autumn. C. humifusa seems to grow equally well in sun or shade, but an open position is doubtless more favourable to flowers and fruit. It is perfectly hardy, absolutely drought-proof when established, and a plant will in a few seasons cover several square yards. The trailing branches layer themselves as they proceed, and any of their rooted pieces afford an easy means of increase.

Rose Mermaid.

WHATEVER may be one's opinion of single roses in general, I can scarcely conceive of anyone seeing a plant of Mermaid with some of its large, broad-petalled suphur yellow blossoms fully expanded and others in various stages of development, without being moved to exclaim upon its remarkable beauty. The foliage of this rose is sumptuous and provides the most perfect background for the pure, clean and cool looking blossoms. One may admire a plant climbing orthodox fashion up a wall, but an infinitely grander sight is to see a plant which has stolen its way between the balustrade of a terrace and tumbled over the face of the retaining wall. That is when this delightful rose displays all its charms, and wherever such a position is available, there certainly should be a plant of Mermaid. I have seen it clambering over a rough old hawthorn, creating a picture of bewitching beauty and I have seen rows of plants on a nursery growing prostrate on the ground, where it is still lovely. I can imagine the glorious effect that might be produced by a clever artist provided with some flowers and foliage of Mermaid and a broad black bowl.

ORANGE GLOBE, ONE OF THE BEST VARIETIES OF TROLLIUS FOR GARDEN DECORATION.

Viola lutea.

OUR native mountain pansy is a plant of singular charm and one that is by no means beneath the gardener's notice. It is an underground spreader and, being a paint that is vigorous enough to contend with the rank sod of its moorland home, it must be used with discretion. It undoubtedly enjoys a cool, but light loam and I have found it an admirable subject for carpeting the ground beneath thin shrubs, for waterside banks, open places in the woodland and heath garden. This comely little pansy will hybridise freely with V. comuta and others. Personally, I like the type best, but the half-breed off-spring are usually very floriferous and interesting. Division is the only reliable method of propagation with V. lutea if it is to be kept true, and its mass of roots affords ample material.

Phlox Laphami.

IT is a queer garden that cannot, with advantage, accommodate a few plants of this really beautiful plant, with its slender stems and pretty lavender flowers. It is always good, whether on a rockery, in the mixed border, or occupying a small circular bed entirely to itself. The plant likes good feeding and responds generously to liberal treatment. Young plants grown from cuttings taken in spring and rooted in sharp, gritty soil in a frame, will produce a limited number of strong, well spread heads or trusses of bloom, but a plant two or three years old will yield a mass of bloom and continue to throw up new growths and flower heads for months.

A Monarch Among Perennial Asters.

HE would be a bold man who would say of any one Michaelmas daisy, "This is the best of the whole family"; but one needs no great courage to declare that Aster Amellus King George is a monarch among the tribe and a hardy border plant of highest merit. There is an air of quality and neatness about the Amellus type of asters which appeals to many who are disposed to look upon the rest of Michaelmas daisies with something akin to contempt, and, although by no means the only good Amellus variety, King George is unquestionably one of the very finest. Nearly every exhibitor of asters at Holland Park Show had a group of King George on his stand, and many spectators remarked on the great beauty of colour and form of this fine variety.

The great secret of securing maximum quality in Michaelmas daisies is to plant single crowns either annually or every second year, and this applies as much to the Amellus section as to the Novi-Belgii. It is not always wise to disturb the plants after flowering, for late autumn planting is attended with some risk where plants have soft, succulent crowns and foliage, and spring planting affords ample time for healthy crowns to develop into fine sturdy plants for September flowering. Over-rich soil is by no means necessary or even desirable for freshly divided asters of the Amellus class; the plants are far better grown hard until the latter end of July, when liberal feeding from the surface may be commenced and carried on judiciously until the first flowers open. A. J. M.

LILACS FOR THE SMALL GARDEN

THE present day race of garden lilacs is the progeny of the purplish-mauve and white varieties of Syringa vulgaris, the wild lilac of the mountainous regions of eastern Europe. No definite record appears to exist of its first introduction to British gardens, but we know it to have been cultivated for more than three hundred years. There is no more popular hardy shrub grown in our gardens to-day, and with perhaps the single exception of the rhododendron, no shrub has been more markedly improved by the hybridist. As the names indicate, a large proportion of the best hybrids in cultivation to-day have been raised in France, and new varieties are still being raised.

The lilac is a shrub that grows and flowers freely equally well in large and small gardens, provided the position is open and sunny. Too often we see lilac bushes crowded and given scant attention in the mixed shrubbery border. Complaints of lilac bushes not flowering are by no means infrequent. This can usually be traced to a large number of suckers being allowed to grow from the base eventually forming a tangled mass of weak branches. A second cause may be neglect to cultivate and manure the ground, while a third reason may be that the position is unsuitable, though this is unlikely if planted in a sunny spot for the lilac is really an accommodating shrub. Given a little attention lilac bushes are good shrubs for town and suburban gardens.

THE SOIL AND POSITION.

While lilacs will grow and flower in most cultivated garden soils, there is a marked improvement in the beauty of the bushes when the ground is a deeply cultivated medium loam, with a good addition of decayed manure, when trenching the soil previous to planting. A heavy, wet ground is the least satisfactory. When this is the only possible position, put plenty of builder's rubble in the bottom spit when trenching the ground, mix in freely light sandy loam, or coarse grit, and raise the soil above the normal level. Light, dry soils can be improved by adding plenty of heavy top-spit pasture loam and decayed cow manure.

The need for planting in open sunny positions has already been indicated, whether in beds, borders or as lawn specimens. The beautiful lawn specimens sometimes seen obviously point the moral to allow the bushes ample space to grow when planted in shrubbery borders.

A mulching of well decayed manure, applied immediately after flowering and when new shoots are developing, is beneficial. A good method to adopt is to vary this with bone meal in alternate years.

PROPAGATION.

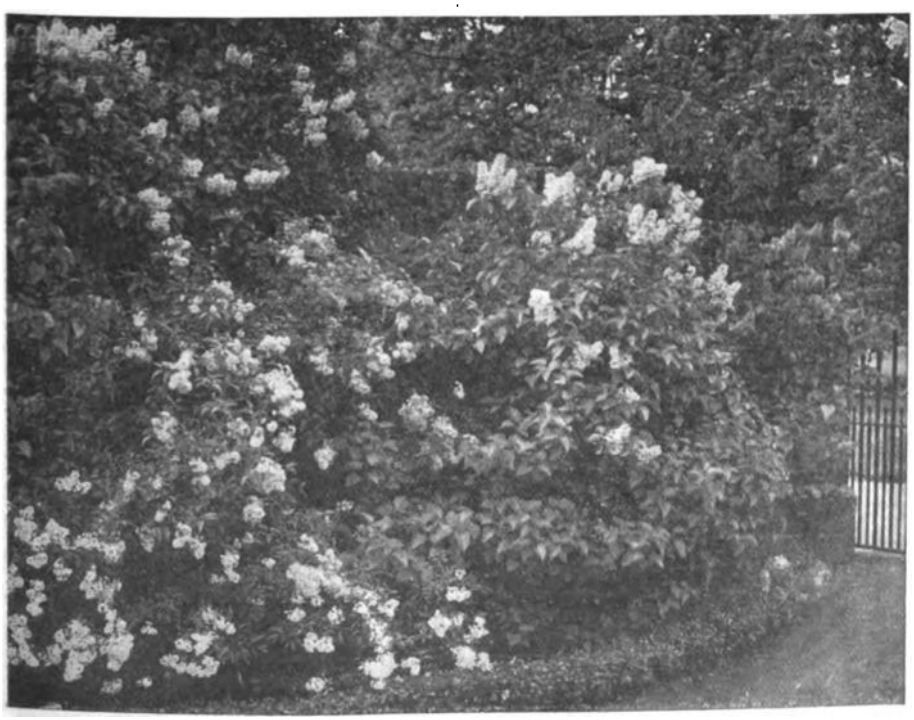
Some comment on the best methods of increasing lilacs will be looked for in these notes, though my recommendation is to purchase plants from a nursery. Whether propagated by layeringor cuttings several years must elapse before the bushes flower. The grafting of new varieties is practised, but this has the undoubted drawback of suckers, which must be persistently removed, whereas, if the bush is on its own roots a sucker or two will help to maintain the vigour of an old bush.

PRUNING.

Though a relatively simple business, this is one of the most important details in the successful blooming of lilac bushes. Too often it is neglected, or pruning is done in winter, cutting off the flower buds, instead of in early summer, immediately after flowering.

On fading, remove the flower trusses and thin the young shoots where crowded, discarding those which are thin and weak. This throws the energy of the bush into the development of a number of strong, healthy growths, which ripen well and mostly mature flower buds, because of the open character of the branches plenty of light and air can reach the shoots.

A SMALL BUSH LILAC OF GRACEFUL HABIT.



LILAC BUSHES ARE EXCELLENT SHRUBS FOR THE FRONT GARDEN, ALONG THE PATH.

CHOICE OF VARIETIES.

The present day race of lilacs are noteworthy for the size of the inflorescences, the large individual blooms and the remarkably rich and varied range of colouring from the purest white to deep wine crimson. It is a matter of personal fancy whether the single-flowered, or the double-flowered sorts are favoured, both have hosts of admirers.

The older varieties, like Marie Legraye, white, and Charles X, purplish lilac are beautiful and should be included in a large collection, but they cannot be included to-day in a limited selection of the best ten or twelve sorts for outdoor cultivation. Because of their freedom of flowering these two sorts are still unsurpassed for cultivation in pots to decorate the greenhouse in early spring.

Single Varieties.—Captain Boltet, purple lilac; Congo, dark red; Hugo Koster, purplish crimson; L'Oncle Tom, dark crimson; Mme. Francesque Morel, violaceous pink; Mont Blanc, a magnificent single white lilac; Pasteur, claret red; Reaumur, dark carmine; Saturnale, bluish mauve; Souvenir de Louis Spath, vinous crimson.

Double Varieties.—Charles Joly, dark red; Condorcet, lavender; Lemoinei flore pleno, pale mauve; Mme. Abel Chatenay, milk white, late flowering; Mme. Casimir Perier, creamy white; Michael Buchner, lilac; Miss Ellen Willmott, pure white; President Fallieres, rosy mauve shaded lilac; President Grevy, bluish lilac; Virginite, pale mauve pink. A. O.

CLIMBING PLANTS FOR OLD TREE STUMPS

IN nearly every case it is worth while leaving the stump of an old tree, for, with careful treatment, this can be converted into an object which will add considerably to the effect of the garden. By planting suitable climbers and ramblers the stumps may be rendered extremely beautiful, especially if they are in an open position where there is plenty of sun and air. Before doing anything in the way of planting round the stump it is essential to prepare the soil well, as this is almost certain to be in a very impoverished state. By far the best plan is to take out the old soil altogether to the depth of about 2ft. all round the trunk and to fill in with a mixture of good loam, leaf-mould and well rotted manure. The trench should be opened at a distance of about a foot from the tree all round, and it might be a couple of feet in width. Generally speaking, it is wise not to plant the climbers too close to the stump as these can always be trained in the desired direction when they start to grow.

Practically all the Wichuraiana and rambler roses are eminently suitable for tree stumps. Of the former one might specially mention Edmund Proust, a fine carmine; Jersey Beauty, yellow; Gardenia, cream; May Queen, coral pink; Paradise, pink and white; and Paul Transon, rose. Among the ramblers there is a very big choice, but the following have been found to do particularly well on tree stumps: Dorothy Perkins, pink, and the White Dorothy; Excelsa, fine shade of red; Hiawatha, crimson; Minnehaha, bright pink; and Albéric Barbier, yellow buds with white flowers.

Lovely effects are certain when the stumps are planted with some of the many fine varieties of clematis. Where the stump has not a very full exposure one might do worse than plant the wilding Traveller's Joy (C. Vitalba), but most people will probably prefer the more handsome garden forms. Among the best are the following, but the list is very far from complete: Clematis grata, white flowers (early autumn); C. montana, white flowers (May); C. Flammula, enormous numbers of small fragrant whitish blooms which are produced in the late summer; and C. Jackmannii, the familiar purple form that blossoms in July and August.

Then there are the honeysuckles, which may be planted in variety. Specially worthy of notice is Lonicera gigantea superba, which in favourable circumstances will grow with great rapidity and produce its large yellow flowers in abundance. Almost as good is L. Hildebrandti, with buff-coloured flowers which turn reddish. Both these honeysuckles were formerly thought to be somewhat tender, but they have proved to be hardy at least in the south. For quick results one cannot well equal the polygonums, especially P. baldschuanicum. This is such a rampant grower that in an incredibly short time it will clothe an old stump and mount up to a considerable height. The display of creamy white flowers continues well into the fall, and in sunny positions the fruit cases often turn an attractive crimson colour.

Other plants which have been noticed as doing well on tree stumps include several species of actinidia. All of these are good, but perhaps the best is A. chinensis, the young growths of which are covered with red hairs. The foliage is large and the yellow flowers are succeeded by berries. Then there is the common Virginian creeper (Ampelopsis hederacea), which is, of course, glorious in the autumn. That splendid convolvulus (calystegia) in both the pink and white forms is a very handsome subject, and on account of its scarlet berries Celastrus scandens is also worthy of note. The hop is a quick grower and the form with golden leaves is always attractive. Many varieties of ivy are suitable for tree stumps, but more distinctive evergreens are to be found among the hardy smilax like S. aspersa and S. rotundifolia. Most of the hardy vines are good, and the following are specially worthy of note: Vitis Brandt, V. Coignetiæ purpurea, V. Henryana, V. purpurea and V. Thunbergii.

L. B.

RAMBLER ROSES ARE EMINENTLY SUITABLE FOR A COVERING.

CLEMATISES, OF WHICH C. MONTANA RUBENS IS ONE OF THE BEST VARIETIES, MAKE A DECORATIVE COVERING FOR TREE STUMPS.

Making Climbers Cling on Smooth Surfaces.

SMOOTH walls or wooden structures do not offer very good surfaces for ivy and other climbing plants. The difficulty is even greater in the case of a sheet-iron fence, which, however it is treated, always presents rather an unsightly appearance. Even if the climbing plants get a start, it often happens that the young growths hang downwards and find the greatest difficulty in getting a hold. By coating the surface with a preparation, which is easily made, it is a simple matter to provide the plants with a surface to which they can cling readily.

Into a pail put four handfuls of cement and half the amount of sand. Now, while stirring with a stick, add water until a mixture about the thickness of rather stiff batter is secured. If the mixture has been made too slack, add a little more cement and sand to stiffen it. This is now applied with a brush to the surface over which it is wished to have the climbers. Apply one coat and, after this has dried, give a second, and even a third. Ivy and all other creepers will be found to cling readily to the surface thus secured, and it is not harmful in any way to the most delicate plant. Where, for any reason, it is thought that the wash will appear unsightly before it is covered by the climbing plants, employ just enough for each year's growth.

It should be remembered that climbing plants should be given a little support at the start, as if they are allowed to straggle about on the ground much energy will be wasted.

FLOWER GARDEN NOTES

Dwarf Phloxes for Rock Garden and Border.

THE best of dwarf phloxes suitable for the rock garden, wall garden or the front of borders are forms of P. subulata introduced to this country over a hundred years ago. So beautiful are they that the late Reginald Farrer says, in "The English Rock Garden," "the day that saw the introduction of P. subulata ought indeed to be kept as a horticultural festival." This is high praise, but deserved, especially when we consider the group as a whole.

P. subulata is dwarf, rather prostrate in habit, about 6ins. high, and the plant forms a compact evergreen mass which is pleasing at all seasons. The small leaves are awl-shaped and numerous. During May and June the plants are masses of flowers; in fact, it is not possible to see the foliage for bloom. Carpets over rocks and down walls 2ft. or 3ft. across are delightful, and no rock garden can afford to be without them. As an edging to the ordinary flower border they are ideal.

The flowers of P. subulata are rose-coloured with a dark eye, and of the numerous varieties mention should be made of G. F. Wilson, a beautiful, free-growing plant with delicious lavender blue flowers. Another fine mossy-habited phlox is Moerheimi, a deep rose pink, the compact Nelsoni, with white flowers except for the pink eye which to many is an additional charm; nivalis, a pure white; and lilacina, electric blue; but perhaps the finest and best of all is Vivid. Here we have a plant not quite so robust as many varieties, but it is unsurpassed with its warm salmon rose or flesh pink flowers, to which no written description can do full justice. No difficulty, however, will be experienced in growing these plants, and no doubt there are several other varieties in commerce that can vie with the above.

Any ordinary soil will suit them, but if it is of a rather retentive nature a quantity of sharp sand and a little leaf-soil should be added. The position is almost immaterial, and except in dense shade, I would not hesitate to plant them anywhere.

Once the plants are purchased it is an easy matter to keep a healthy stock, and after the flowering period—say, in July—the young shoots, made into cuttings, will readily form roots if placed in a cold frame or under a handlight. Sandy soil is needed, also shade from strong sunlight until they are rooted, when the lights can be removed. By the following spring good flowering examples will be available for transferring to their final quarters. No garden lover will regret adding these charming subjects to his collection. —T. W. B.

A COMPACT AND FREE FLOWERING PLANT OF PHLOX SUBULATA NELSONI, WHICH EVERY AMATEUR SHOULD GROW IN HIS ROCK GARDEN OR AS A BORDER EDGING.

Notes on the Plant Order for the Autumn.

ALTHOUGH it may be stormy and wet out of doors, interest in the garden does not diminish. At the end of the growing season there comes an excellent opportunity for reviewing what has happened during the past year. A careful study of any plant catalogues which can be secured will be found to be most helpful. The majority of these are far more than mere lists of plant names and will well repay a careful study. It is wise, before making any decisions, to think well about the habits and requirements of the plants in question. Often a special variety of a plant will give much better results than the original type and, in many cases, the additional cost is hardly worth bothering about. When in any doubt as to whether certain plants would be likely to be a success in the garden, it is always worth writing to THE GARDEN or the firm with which one has decided to deal. In doing so, be careful to give as complete particulars as to soil, local climate and general conditions as possible. Usually the grower will be able to give valuable suggestions as to the best subjects for special positions such as the very shady border or the dry sunny bank. Before despatching the final list check it several times to make certain that it is correct. Plant orders should be despatched as soon as possible, for at this time of the year there is a great demand for plants.

WHEN THE PLANTS ARRIVE.

It is always an exciting moment when the plant order is delivered. Naturally, it is well, as soon as possible, to check the goods, as, although most firms handle orders with great accuracy, there is always a chance that some error may have arisen. Open the packages methodically; remember the plants are living things and that roots and shoots are often easily damaged unless treated with care. Keep a sharp look-out for the labels, as it is easy to get these separated from the specimens, and it is most annoying to find that you have a number of plants without any names at all. Where the order is a large one it may not be possible to get everything planted quickly, or for some other reason there may be delay in setting the plants in their permanent quarters. Proper planting is of such supreme importance that it is far better to defer the business until there is plenty of time rather than to do it carelessly, in a hurry. The roots will come to no harm if they are placed out on the floor of a shed, and, after being sprinkled with water, covered with matting or similar material. Fruit trees, ornamental trees, roses, shrubs, etc., should be packed closely together in a shallow trench and then lightly covered with soil. Never, on any account, allow the roots of plants to be exposed to the drying action of the air save for a very short while. Small roots shrivel and die within an hour or so unless they are surrounded by moisture, and, if this happens to any extent, a serious check to the plant as a whole is the result. Any roots that have been damaged in lifting, or on the journey, should be cleanly cut through beyond the injured portion with a sharp knife.

The ground in any situation should be well prepared in advance of planting. Of course, the wise gardener, even before he despatches his order, will have given attention to this business. Matters should be so far advanced that, on the day when the actual planting is to be done it only remains to dig the holes in which the subjects are to be inserted. The plants can then be taken a few at a time and quickly inserted in the positions where they are to remain.—S. L. BASTIN.

Hirsute Chrysanthemums.

IT has been said that the miracle of to-day becomes the commonplace of to-morrow, and certainly the introduction many years ago of hirsute, or hairy-petalled, chrysanthemums, if not regarded quite in the light of a miracle, at least created a sensation, and there were those sanguine enough to predict for them a great future. In those days I was connected with an association which made a practice of obtaining for its members every year a few of the latest novelties, and it fell to my lot to have a share in the growing for exhibition plants of Louis Boehmer, a mauve pink, the petals of which were hairy and were favourably commented upon at the time. If my memory does not lead me astray, I think the following season saw the advent of a white sport of this variety. Then followed such varieties as Princess Henry (pink), Hairy Wonder (reddish bronze) and E. F. Taggart (yellow). It is seldom that one meets with any of them to-day, and one may search the lists of the principal growers of chrysanthemums in vain for them. It is a pity that they were allowed to drop, but, like many other sorts, one recalls to mind hirsute varieties which appeared only for a little time. One point concerning them I well remember—that to have best results only crown buds were worth considering, as on the terminals these hairy

Digitized by Google

wonders were less of a wonder. Is it possible that some grower of the old school of chrysanthemum fever days, reading this note, still retains interest in and grows them?—W. F.

A Good Sea Holly.

SOME confusion exists among gardeners regarding the true Eryngium planum, one of the sea hollies. It is less common in gardens than several other species, and some have called E. alpinum by the name of planum, on account of its basal leaves being undivided. But the two plants are quite distinct. While E. alpinum has large heads of inflorescence, those of E. planum are small. The basal leaves of E. alpinum are also much larger than those of E. planum and are prettily serrated. The colour of E. alpinum is also considerably brighter blue than that of E. planum, and it is, altogether, of much greater beauty. Yet the smaller headed E. planum, which has been in our gardens since 1596 at least, is not to be despised, and, as its inflorescence can be dried for winter decoration like that of E. alpinum, it may be useful in other ways than as a border plant. It grows about 3ft. high, but more frequently about 2ft., and is interesting as well as pretty, owing to its being an umbelliferous plant of real garden value. It may be grown in ordinary garden soil and generally flowers in July, August and early September, according to the district.—S. ARNOTT.

Five Interesting Delphiniums.

MOST gardeners associate the name delphinium with tall spikes of handsome blue flowers in the July garden, and though this is quite correct in nine cases out of ten, there are delphiniums which exhibit other colours no less attractive.

All the delphiniums are easily raised from seed, and those who have been reckless enough to experiment with a few twopenny packets of seed of some of the different species of this family are looking forward to seeing their seedlings flower next year.

Belonging to the buttercup family the seedlings bear a strong family likeness to the crowroots, so much so that it is quite easy carefully to prick out an occasional buttercup among a batch of seedling delphiniums.

Perhaps one of the most interesting of the less common delphiniums is D. nudicaule. In common with the blue perennial hybrids, this plant will flower the first year, if the seeds are sown early enough in the spring. It throws up a loose spike of scarlet flowers some 12ins. high, and though at first sight one would hesitate to pronounce it a delphinium at all, on closer examination it is seen to possess the same blunt spur which has given these plants their name, which means "dolphin," because this spur was supposed to bear a resemblance to a dolphin's head.

Another red delphinium worth growing is D. cardinale, which flowers in August and is a native of California, which is also the home of D. nudicaule.

If these scarlet delphiniums are somewhat new to some of us, surely a yellow delphinium may also be classed as a novelty. D. sulphureum is a perennial with spikes of yellow flowers some 3ft. high.

D. chinense or grandiflorum is a dwarf species with dark blue flowers, eminently suited to the rock garden. It comes from Siberia, the home of several other species, and it was one of the progenitors of our blue garden hybrids.

D. cashmirianum is another good dark blue species from Kashmir, which only attains a height of some 15ins. and should therefore find a place among rock plants.

E. CAHEN.

A SELECTION OF PEARS FOR THE AMATEUR

JARGONELLE.—One of the earliest pears, and for that reason I must include it. It is suitable for a wall, but the growth is rather too weak and spreading for a bush. Not a very regular cropper, and must be eaten as soon as picked, as it will not keep. A medium-sized fruit, rather long and of a greenish colour sometimes with a faint flush.

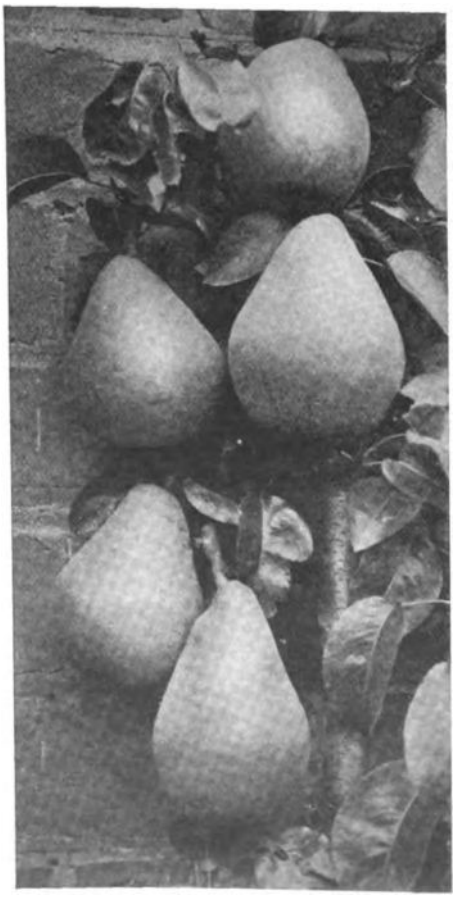
Williams' Bon Chrétien.—Need I say a lot about the ever-popular William (the American Bartlet)? A tree of medium vigour, which needs careful pruning when grown on the free or extension system, it has one great fault, it is very subject to scab. The fruits are of medium size and ripen in September.

Doyenne Boussoch.—This pear does not seem to be well known, and although not of first-class flavour, it is of good appearance and, above all, is a most regular cropper. I have not seen this pear grown as a bush, but as a standard it is most useful, as one can always depend on it bearing unless, of course, we have a very bad spell of weather at flowering time. The fruit is roundish, of medium size and of a lovely golden yellow colour when ripe, sometimes having a red flush. This pear cooks well before ripe. It ripens during October, but will in some years keep till November.

Maréchal de la Cour (Conseilleur de la Cour).—Another mid-season pear, ripening in October. Of vigorous growth, this pear is to be recommended on account of its regular cropping habit. The flavour is not of the best, but it is quite good. The fruit has a narrow waist, is pale yellow in colour and russeted, quite a nice-looking fruit and, speaking from a grower's standpoint, sells well.

Conference.—This pear is sometimes called Ladies' Fingers on account, I suppose, of its very long, thin fruits. Ripening just after the preceding variety, it is a good pear, very resistant to scab, a prolific cropper and a well flavoured fruit. The skin is rather tough and needs to be removed if the fruit is to be really enjoyed. An upright-growing variety, the weight of fruit often brings the branches down so that the clusters of the distinct long fruits hang well below the leaves. I should recommend every amateur to have a bush of this variety.

Beurré Hardy ripens at the end of October. A fine-flavoured pear of good size, Beurré Hardy lives up to its name, and is hardy and a regular cropper. On referring to Bunyard's Hand List of Hardy Fruits, I find that this pear was named after a Mr. Hardy. However, it is hardy by name and by nature. A "lumpy" shaped fruit, if I may be excused such an expression, has a russety skin and is often irregularly shaped, not enough, however, to detract from its appearance.



LUSCIOUS FRUITS OF THE PEAR DOYENNE DU COMICE GROWING ON A WALL.

Louise Bonne of Jersey.—This pear ripens at the end of October. Of small size and a greenish yellow colour, with a dark flush, its flavour is very good—I think "honey sweetness" describes it best. The skin is quite smooth and sometimes shiny, with conspicuous dots. Not a very strong grower and inclined to spread, I would not class this as one of the most regular croppers. However, it is well worth its place on account of its fine flavour.

Durondeau.—A really handsome fruit, which is in season at the end of October and into early November. Large and with a long tapering neck, this variety often has a shallow gulley along one side of its fruit. The flavour is good and it is a good cropper. Brown in colour when quite ripe and covered with small dots, this pear is easily remembered and well worth growing. Its fault is that it is rather subject to scab.

Doyenne du Comice.—The aristocrat among pears. The fruits are of medium size, "dumpy" in shape and of exquisite flavour. A yellow-coloured pear with a slight russet, it is of moderate growth and makes a good bush. It suffers in cold springs and well repays the shelter of a wall.

Marguerite Marillat.—An enormous pear, ripening in mid-October. The flavour is distinct, but cannot be classed as the best. Rather oblong in general outline, but often misshapen, it is a good cropper and is very popular for exhibition. When ripe it is of a rich deep yellow colour with a red flush on the exposed side. This pear must be handled very carefully, as it bruises very quickly and the dark reddish brown bruise soon shows on this brightly tinted pear.

Emile d'Heyst.—A most distinct tree. The leaves curl upwards and show the whitish under sides, making a vivid contrast to the very shiny upper leaf surface. A very spreading grower, this makes a good bush or standard. Being very hardy, it is satisfactory as a standard in the Midlands. It ripens in early November and then changes from a dull green to light yellow, covered with tiny russet dots. The flavour is good and the fruits of medium size.

Catillac.—The best stewing pear. It will keep until April, and is large and roundish in shape. It makes a rather spreading tree and is a fairly regular cropper. The green fruits are at present very hard, but after Christmas it is fine for cooking. N. D. H.

THE BUSY MAN'S PAGE

Hardy Perennials for Cutting.

PERENNIALS which are suitable for cutting as well as garden decoration are a great asset, particularly to the busy man. Where possible a border should be set aside for them, so that the beauty of the general herbaceous border is not interfered with by cutting flowers for the house. Here are a few which can be planted this autumn. They are all hardy and easily grown.

ASTER ANITA BALLARD.—*Cornflower blue. September. 5ft. One of the best of the Michaelmas daisies.*

CHRYSANTHEMUM MAXIMUM MAYFIELD GIANT.—*Snow white. August. 4ft. A large-flowered Shasta daisy.*

COREOPSIS GRANDIFLORA, PERRY'S VAR.—*Rich golden yellow. June to September. 2ft.*

ERIGERON B. LADHAMS.—*A rose pink fleabane. June to September. 2ft.*

GAILLARDIA MRS. J. MCKELLAR.—*Crimson-scarlet, with gold band. June to September. 2½ft. This blanket flower is highly decorative.*

HELENIUM AUTUMNALE RIVERTON GEM.—*Red and gold. August to October. 4ft.*

Treatment of the Fire Bush.

IT is very noticeable as one travels about, that the many wall plants of this popular climbing shrub vary in a remarkable manner in regard to the quantities of berries carried. Questioned as to why plants in evident robust health do not carry berries, the jobbing gardener usually declares "it's the season"; or if it happens that another plant within sight is carrying an abundance of its coral beads, then it is the soil that is to blame. In the majority of cases it is the jobbing gardener's shears that should really be blamed, for they are far too frequently used as ruthlessly as they are on an overgrown hedge. It is wrong to cut back all the growths of Cratægus Pyracantha to a level-faced frontal as even as the wall behind the plant. The secret of berries lies in knife or secateur pruning, cutting out the densest short growths and tying in long, vigorous young shoots during the summer growing season, just spurring these same growths the following early spring. My practice with the plant is not to confine pruning to one particular season, but to thin out a few both old and young growths as they tend to become crowded, doing some tying in at the same time, and then remove entirely old branches that have borne heavily, filling in the space with young wood.

Hedge Trimming.

A NEATLY trimmed hedge is a splendid set-off to a garden. Many hedges are spoilt from want of proper and seasonable clipping and trimming. It is generally when hedges are young that they are permitted to run riot and grow out of shape. If the hedge has been well planted, and is growing well, it will not be at all difficult to keep it in proper form, if trimmed carefully once or twice a year with the shears or hedgebill. The shears makes the better job, especially in the trimming of privet or beech, but an expert at plying the hedgebill will make an admirable job, nevertheless. For the first few years the young growth should be cut fairly hard in, especially on the sides. If the young hedge looks thin and irregular, it must be cut well down to induce a thicker growth.

The late autumn is doubtless the best time to trim hedges, but they may also be trimmed during the summer, though not quite so severely as in the autumn. The hedge is clipped more easily if done before the wood gets ripe and hard. The hedge looks neater, too, and is in less danger of being broken down with falls of snow, than when the trimming is delayed until winter comes.

A Protection for Young Trees.

IN many districts rabbits and hares cause considerable damage to young fruit trees, and young ornamental trees, by gnawing away the bark. This they are specially addicted to do during spells of frosty weather, when other food is difficult to obtain, and it is most annoying to see promising young stock spoilt in this manner. The following method has proved an effective protection.

Take equal quantities of fresh cow dung and good stiff clay. Mix well together and add water until the whole is of the consistency of a smooth cream. Then add to each bucketful a good tablespoonful of tincture of asafœtida and stir well together. This latter is a vile smelling liquid obtainable from the druggists. Apply the mixture with a brush to the trees up to a distance of 2½ft. from the ground and repeat two or three times during the winter. For bushy subjects, such as cytisus, make the mixture a little thinner and apply with a syringe. See that the work is done well.

Decorative Spring Bedding.

THIS is the time of year when attention must be given to planting for next year's spring garden, and in this connection we would draw attention to the planting of tall Darwin tulips in association with forget-me-nots. The accompanying illustration, shows the decorative effect which is to be obtained by this pleasant combination. Seven different varieties are used in this bedding scheme namely, King Harold, purple red; Mme. Krelage, deep rose; Farncombe Sanders, rosy scarlet; Pride of Haarlem, carmine rose; Victoire d'Oliveira, dark red; William Pitt, dark scarlet; and Clara Butt, salmon pink. Six of these are fully 4ft. high and the handsome blooms look exceedingly well against the blue carpet of the forget-me-nots.

A MOST EFFECTIVE SCHEME FOR SPRING BEDDING IN A SMALL GARDEN. TALL DARWIN TULIPS AND FORGET-ME-NOTS.

Before Using Fertilisers.

TOO many gardeners seem to regard manures as universal "cure-alls" which are sure to lead to almost magical results when applied. Before actually using manure of any kind it always pays to think over the following points:

However good the manure may be it will never take the place of proper cultivation.

The more thorough the culture the less should be the need for manure.

Do not go on applying manure without bearing in mind the fact that it may be largely wasted if the land is deficient in lime. As a rule lime should be applied to the garden every three years.

Unless a plant is really healthy it will not benefit by the application of manure.

Light, warmth, air and water are more needful than ever when a plant has been manured.

Never let manure come directly in contact with the roots of a plant.

It is really harmful to seedlings and cuttings to apply manure.

Manure is not needed by plants that are flowering or fruiting as then growth is almost stationary.

Give the manure on the principle of "a little and often," as the roots can only absorb a certain amount at a time. One cannot cram any crops in the way that the poultry keeper fattens up his birds.

Simplified Bulb Growing.

FOR many years I have been interested in the growing of hyacinths, daffodils, tulips and other bulbs in sphagnum moss, or failing this, moss from old walls, which is a splendid substitute. Leaf-mould is also a suitable rooting medium and gives good results. These materials are clean to use, simple to manage and completely successful from every standpoint.

A little charcoal or small pieces of lime rubble may be mixed with either the moss or leaf-mould, but this is not essential. The most important point to remember is always to see that either the moss or leaf-mould is sufficiently moist. When a large number of any particular bulbs has to be grown, I use boxes 3ins. or 4ins. deep and 18ins. long by 12ins. wide. At the bottom of these I place (if leaf-mould is used), rough rotted leaves, with a covering of finer mould. I then embed the bulbs, almost touching each other, in this layer and fill up to the neck of every bulb with more leaf-mould. The boxes are placed upon each other in tiers of seven or eight, in any safe place, covering the top one by inverting an empty box over it. I leave the boxes untouched for some weeks, until they show signs of growing by a profusion of roots pushing out of the bottoms of each box. The boxes are then exposed to the light and transferred to a warmer atmosphere. The same method is used with moss, but in this case, when the roots have filled the box or boxes, a strong pair of scissors will cut up the moss into squares with whatever number of bulbs one wishes to have in any pot, pan, dish or bowl. With leaf-mould a trowel or hand fork will divide them just as one wishes. Having grown thousands of all types of bulbs as described, without a failure. I pass this method on as one of the very simplest and surest means of growing bulbs.—A. G.

HARDY PLANTS FOR SMALL GARDENS

Many amateurs find it difficult to make a selection of hardy plants for stocking their garden and to determine where to plant the particular kinds. The following list of subjects, together with their flower colours and height, may prove helpful when a choice is made this autumn. All are plants which call for no special care in cultivation.

IN acquiring plants for suburban gardens to-day, the trend lies in the direction of those which not only beautify but are of service for providing flowers for cutting over as long a period as possible, and this is one of the reasons, I think, why those of a hardy character are so much in evidence.

The time has gone by when the display consisted mainly of those which, owing to their fleeting character, were only tenants for a few months and then died off. In hardy plants we have a wide selection that will make the garden gay, and most of them, at any rate, improve with keeping. The approach to winter may not be opportune for getting in some of them, but we can, at least, be making our plans, preparing the ground, and selecting what we desire. The difficulty, if there be one, is not in finding what will be suitable, but in limiting our choice from the many available, consistent with the size of our garden. For the benefit of anyone scanning these notes and who may have in view the inclusion of hardy plants in his garden, I have drawn up a list of plants that may be relied upon to do well in a suburban garden, indicating those which prefer shade or a partially shaded position, and those which are best accommodated in a sunny position. Those marked * are specially useful for supplying flowers for cutting, while those marked thus, †, will grow freely on chalky soils.

THE ORANGE PERUVIAN LILY (A. AURANTIACA) IN FRONT OF A SUNNY SOUTH WALL.

SHADY POSITION.

THE FRUIT AND KITCHEN GARDEN

Storing Turnips During the Winter.

IT is a fact that turnips will keep very well for a considerable time if allowed to remain in the beds in which they grow; but this is not always convenient, for the ground may be wanted for some other crop, or it may be necessary to give it a good digging for that purpose. Turnips can be stored in sheds and other buildings, but by being heaped together there is danger of one unsound root setting up trouble among the good ones, as with other root vegetables; it is, therefore, preferable to store turnips in the open ground where there is more room.

One way of storing turnips so that there is no possibility of contamination by any bad roots, and ensuring that no turnip touches its neighbour, is to earth up the turnips in the beds without removal therefrom; this especially applies to light or sandy soils—it would not be advisable in heavy or wet ground.

In the latter circumstances it would be better to take out a trench a foot or less deep, and place the turnips in a row as if they were actually growing, with ample space between each root. Then cover the roots by filling in the trench with sand or light soil, and there may be substituted leaves, litter or straw, with a light covering of soil to keep it in place.

Under both systems the turnips will keep sound and fresh, and can be got at easily when required. Cut the tops first of all—not too close, or it may induce sprouting.

These remarks apply to swedes, and may be extended to kohl rabi, winter radishes and, perhaps, carrots. —H. A. DAY.

How to Obtain Early Peas.

IN order to have peas at the earliest possible opportunity next summer, seed must be sown in autumn and as early in the month of November as possible. If the ground was richly manured for the previous crop no more manure is required, as is the case when peas are grown on old celery or autumn cabbage ground; if the soil is not rich, some manurial matter may be dug in, and dug in fairly deeply. In exposed sites a sunk seed-bed is best, *i.e.*, the seeds are to be sown in the bottom of a drill, not on the top, the side ridges protecting the seedlings from strong winds. On the level a board on edge or twiggy stakes inserted alongside serve the same purpose. Again, there must be a "run" for water, because water stagnating round the plants in winter is highly inimical to their free and continuous development. Round-seeded varieties are, as a rule, more hardy.

There are many who find that, even with thick sowing and protection to the seedlings, outside sowings are not always profitable. The only alternative is to sow in frames and to keep the plants there until the really severe weather of winter is past. I have tried sowings from which the seedlings were taken one by one and dibbled in the borders outside; I have also sown seed in boxes and in shallow metal or clay gutters from which the seedlings were transplanted with the ball of soil intact. The most suitable plan I have found is to sow the seeds six to twelve in each pot and then to plant out at 12ins. or 18in. intervals in spring intact. This plan is economical in time and space; the clumps spread when they begin to grow outside and the crop is always good. A sandy loam without any manure is the best compost to use, and when the seedlings are an inch or two high, ample ventilation must be given in the frame. —LANARKSHIRE.

Rotation of Crops.

THE intensive system of horticulture in vogue everywhere to-day demands a scientific rotation of cropping, in order to secure maximum results from minimum expense, labour and soil area. The first advantage lies in economy of manurial matter; different plants take up different food salts from the soil, and these in ever varying proportions; shallow plants tap surface contents of the soil only, while deep rooters reach right down to the subsoil. Healthier plants are also ensured, for it is recognised that, unless in a few exceptional circumstances, continuous cropping with one plant soon brings about deterioration, while plant diseases and insect pests secure a firm hold and make greater ravages on the crop. Thirdly, bacterial action is stimulated by a change of crop; only lately has this fact been securely established, and it explains many benefits formerly recognised but only vaguely understood. For many years, too, it has been known that certain crops prepare and, at times, enrich the land for other crops; rotation takes advantage of this, whereas cropping repeatedly with one crop ultimately urs the osland and reduces fertility.

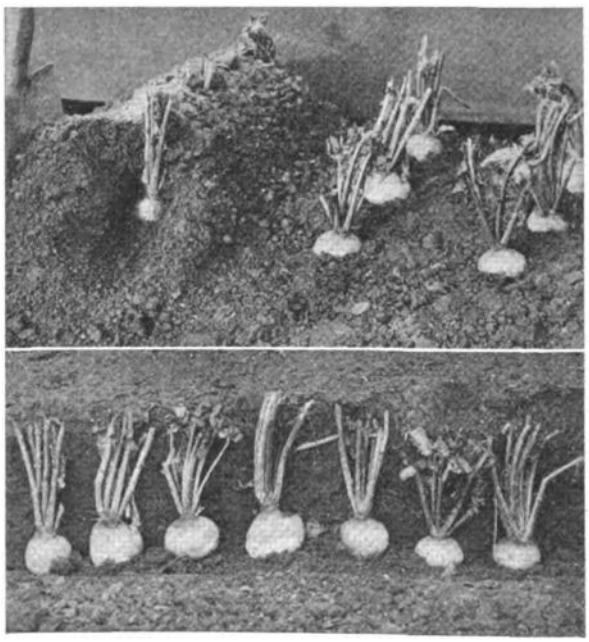
In the average garden a long rotation is not possible; probably a three-year rotation will prove the most acceptable, and we give here one system which has proved of the very highest advantage and profit. The ground is divided into three parts, figuratively and not by hedges or paths; in one plot is grown Selection A, in the second Selection B, and in the third Selection C. Next year Selection A is grown on the second plot instead of the first, B is grown in the third plot and C in the first. In the third year A is grown in the third plot, B in the first and C in the second.

Selection A.—Early potatoes followed by endive and lettuce; mid-season potatoes; late potatoes; early turnips in succession early cabbages, cauliflowers and sprouts.

Selection B.—Shallots, spring onions, winter onions and onion sets; parsnips; beet; carrots; parsley; the seed-bed for annuals, biennials, etc. In this case little, if any, manure is needed, except for the onion crops.

Selection C.—Beans of all kinds; marrows; peas; celery; leeks (after spinach); late peas; lettuce and salads. Some of these crops need a lot of manure; others need just a little.

In all cases, of course, catch crops can be raised on vacant soil, while, often, a winter or spring crop may be had before tender stuff is ready to be planted out in spring. The pod-bearers in C and the richly manured celery and leeks prepare the ground well for parsnips, carrots, etc. The latter, which get no manure, are followed by deep-rooting crops which need manure in plenty. The lime dressing so essential to good gardening, would come in best as soon as Selection B was harvested, a third being treated each year in this way and the whole every three years.—CLYDESDALE.



An easy method of keeping turnips during the winter is either to earth the soil over them or to store in trenches with a covering of light soil.

Propagating Globe Artichokes

GLOBE artichokes only continue to yield produce worth having up till they are three years old, thus fresh plants must be propagated in order to keep the stock young. This is best done by means of suckers, these being found to develop freely round the old plants. They may be detached from the parent plants about now, or from mid-March to mid-April. Provided it is intended to carry out the work this autumn, one way to proceed is to scrape away the soil from around the old plants and then to slice off the suckers with the aid of a sharp knife so that each one has a piece of the main stock attached. Although not essential, provided the suckers possess a piece of the old stem, the endeavour should be to have some roots adhering also. Having secured the required number of cuttings, replace the soil firmly round the old crowns. Another way is to lift an old root or two as necessary and separate into pieces, each with a sucker. Now pot up the suckers singly into small pots of good, light soil, give a watering and then plunge the pots to the rim in ashes in a cold frame for the winter. Keep the frame close for a week, but subsequently admit air freely on all favourable occasions. Then when the proper time comes in spring the young plants may be hardened off, turned out of the pots and planted into permanent quarters. Globe artichokes require well prepared ground, thus as a favourable opportunity offers during the coming winter, the sites should be deeply worked and a liberal dressing of manure applied in readiness for the reception of the young plants. Leave the surface as rough as possible until ready to make the final preparations for planting. —T. W. O.

Rhubarb.

DURING the winter the rhubarb border ought to be deeply dug and a fair proportion of manure or manurial substitutes, like shoddy, wool fibre, etc., incorporated in the soil near the crowns. Artificials never give quite so good results as humus-forming natural products. At the same time, too, large roots may be cut down. Probably the best plan is to lift the clumps entirely and to replant strong "buds" from the outside, keeping the rest for forcing purposes. While rhubarb may be grown for very many years on the same site, a change every five years is distinctly beneficial.

Digitized by Google

Failing a change, the roots may be lifted, the soil trenched and manured and the roots replanted on the same site. Growers of rhubarb know well how a root lifted and inverted so that the roots are exposed to all weather conditions for a month always has a tendency to come into growth more readily and more strongly after replanting or in a forcing pit. I invariably do this to get an outside crop a few weeks earlier than it might otherwise be, and all roots intended for forcing are treated in the same way. Whenever deterioration sets in, betrayed by the production of thin weak stalks and by a loss of quality, the best plan is to discard the roots at once.

New stock can be raised from seed easily or readily purchased. Most growers prefer varieties with nice red stalks, like The Sutton, Paragon, Linnæus, St. Martin's, Victoria and others. A few prefer the green kinds and those which have monster stalks, like the Monarch, Robson and so on. Victoria, possessing both properties, is a good variety for the small garden. The newer Perpetual rhubarb has a longer season than any of the others. In all cases when stock is raised from seed, see that the small amount needed is obtained from first-class stock.—LANARKSHIRE.

Renovating Fruit Trees.

MANY small orchards and plantations of fruit trees are well kept and in a fruitful condition, but there are far too great a number that have been neglected and allowed to fall into decay. Some are beyond hope, but others may be restored to fruitfulness if prompt attention is given.

Where it is a case of old age, stunted growth and injury from animals and other causes, it is really not worth trying to restore such trees to fruitfulness. But if unfruitfulness is caused by faulty pruning, lack of pruning, bad cultivation or neglect of insect pests and fungus, then, with care, they may be restored to a fruitful state.

Renovation includes manuring, pruning, cleaning, eradicating insect pests and fungus, summer spraying, winter washing and good all-round cultivation.

The proper treatment for overcrowded plantations and orchards is to dig up every alternate tree to give ample room for the permanent trees. The treatment is drastic it is true, but it is the only way to have healthy and fruitful trees.

Many fruit trees fail through neglect of winter pruning. Some growers believe that standards can look after themselves. Although their treatment is not the same as cordons and bushes, which are spur-pruned, the work of thinning their heads—that is to say, removing crossing branches, cutting out from the centre of the trees the strong growths, shortening branches of a spindly growth, that are unable to bear a crop without breaking—should be carried out yearly. Sun and air can then play upon all parts, resulting in well ripened and nicely finished fruits. After pruning, all neglected fruit trees should be sprayed with a caustic soda solution to cleanse the trees from moss and lichen, which harbour insect pests.

In cases where winter pruning has not been practised for some years, the heads become thickets, with little, if any, fruiting wood. Apples, pears and plums, not too much crowded, may be carefully thinned. Another cause of unfruitfulness is insufficient manuring, the trees assuming a poverty-stricken appearance, with poor growth and leaves of a yellow colour. Frequently is this state of affairs to be found in grass orchards. Grass should be cleared away from around the base of each tree and a mulch of well rotted manure applied. Grease-banding must not be neglected.—F. H.

Old Wall Trees.

WALLS form a valuable asset to a garden, and as wall space is so precious it should not be wasted—left uncovered or covered with worthless trees. The latter may be trees of choice varieties of fruits, but if the trees are in a bad condition they should be thoroughly renovated or replaced by young stock. I once heard a very able gardener say "I would much sooner undertake the renovation of old vines than plant young ones." Being young myself at that time, I thought much about what he said. Since then I have renovated many vines and planted many young ones, and after nearly forty years' experience I do not hesitate to say I would much prefer to plant young vines. The same remark applies to wall trees. If the trees have been neglected they can, certainly, be "pulled round" again with care; but if the branches are very old and diseased or the roots are in similar state, then remove all roots and branches and plant young trees after thoroughly overhauling the soil and preparing it for their reception. There are numerous specimens, old, but favourites, in our gardens and the owners do not like to dispense with them. Well, in such cases, we should have in readiness a nice lot of fibrous loam and rotted manure, also lime for the special benefit of stone fruits. Begin now to take out the original soil, exposing the roots, and replace it with the prepared compost—three parts loam to one part manure, with one peck of lime per tree for stone fruits. Well work the soil round and under the roots, notching the latter in places and making all the new soil very firm. Then water and apply a substantial mulch. Dress and clean the branches, cutting out decaying parts, rectify errors in overcrowding, lay in new wood where advisable, and make good the face of the wall where it is damaged.—G. G.

WHAT OUR READERS SAY

A NOVEL ROSE BED.

SIR,—This little suggestion may be useful to anyone who wants in a corner of their lawn a rose bed that is a little out of the common. There are four outer posts all connected to a centre one by wooden chains. The centre post is 1ft. higher than the outer ones. Rambler roses are trained up these posts, and in the beds underneath hybrid teas are grown. The wooden chains are made from fir: holes are drilled the length of the drill and then each piece of chain is sawn off, and the whole threaded on stout galvanised wire.

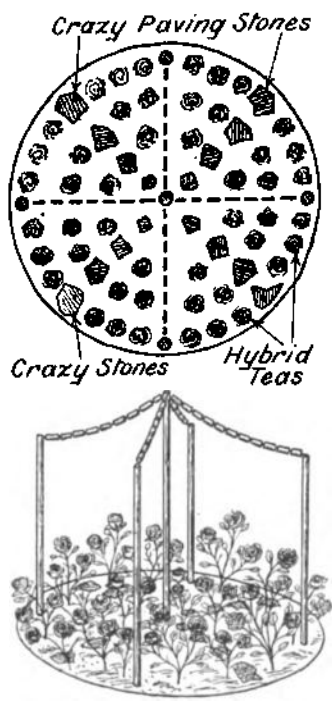
The bed should have a good camber.—S. WHITING.

PACKING COLLECTED PLANTS.

SIR,—I have just had brought to my notice an enquiry in THE GARDEN about how to pack alpine plants for sending home when collecting abroad. Unfortunately, I have not the letter by me, but the writer asked for my experience in this matter, and I am very happy to comply.

In these days of uncertain posts, I never send my plants home from the Alps, but always bring them home with me. I tried sending by Grande Vitesse in 1919, but the plants took three weeks on the way, and, although they had taken little harm, I have not repeated the experiment since.

In the days when one could send by post, I removed all soil from the roots of the plants, packed with a little almost dry moss, and sent in air-tight biscuit tins. At the present time my plan is to remove every scrap of soil from the roots; in some cases I even wash the plants free from soil, and then leave them exposed until the surplus moisture has dried off them. Next, I roughly sort them into their various kinds, arrange them in



bundles with a very little moss round the roots, wrap tightly in newspaper, then pack them as tight as they will go in whatever I have taken to carry them in. Sometimes I have used a suit-case and sometimes a canvas hold-all—one of those green canvas pillow-cases used for soiled linen. I should like to emphasise the very dry state in which I pack the plants, my theory being to keep them practically dry and practically air-tight, so that no evaporation goes on and no fermentation.

The downfall of most amateurs is that they simply cannot resist "just sprinkling the poor dears" with a little water when packing, with the result that 90 per cent. of the "poor dears" emerge at the other end in a state of very smelly putrefaction.

When collecting I usually let my plants accumulate for several days. Remove the soil superficially at the time of collecting, and save up for a big morning's packing at intervals, when I do the final cleaning away of soil.

During the intervals between collecting and packing, the plants usually reside in a compact heap covered with damp towels, on my bedroom floor. By this method I can successfully bring home plants and keep them going for a fortnight, and even three weeks, and I think I am right in saying that I do not lose more than an average of 5 per cent.

The method of treatment on arrival in England is, I think, quite as important as the treatment during transit. What I do with the majority of the plants is to heel them in in a bed of pure silver sand, beneath which is a stratum of leaf-mould or other nourishment. The plants are kept shaded and close for a week or so, and then gradually they are hardened off. They soon plump up, and before long begin to root into the silver sand,

Digitized by Google

and as they begin to sit up and take notice, they are dealt with and either planted out or potted.

Occasionally, when I have seen some very special variety of a plant I have been tempted to dig it up with a little sod of soil complete, with the idea of bringing it home undisturbed, but this method has almost always proved a failure, and time after time special forms have come through, even when quite tiny scraps, when treated and packed like the others.

I never hesitate to collect either fibrous-rooted plants or bulbs in full flower, and I always think the plants are far easier to move when in growth than when dormant.

I hope these hints may help to keep at any rate, a proportion of the plants which are annually dug up by enthusiasts in the Alps, from the deadly sponge-bag method of packing.—CLARENCE ELLIOTT, *Stevenage.*

MICHAELMAS DAISIES.

SIR,—The photograph conveys some faint impression of the massed beauty of a border of these, the last outdoor flowers of the year. It fails to give an adequate representation of the length of the right-hand bed, which is exactly 100ft., the plants four deep and all staked outwards with four or more canes, so as to afford the fullest possible flowering surface.

Starworts bloom so late in the season that it is scarcely possible to grow them among other herbaceous plants, in that they would present merely a green blank in the colour scheme. Instead I devote a side walk to their display, but use the fore-front of the border for stocks, nemesias, clarkias and other annuals which can be pulled up before the daisies get into their stride.

This year the drought has rendered heavy watering necessary during the month of September, and, even so, mildew has attacked certain of the plants, while a few others have wilted and been replaced, a safe operation which in no way interferes with the flowering, provided a sufficient ball of soil is lifted with the roots.

One of the chief charms of Michaelmas daisies is the attraction which they have for butterflies. 1926 has been a Small Tortoiseshell year. The wonted wealth of the Red Admirals and Peacocks has failed, but Commas have visited the border in fair numbers. The verge at the foot of the daisies is ordinary thrift, from which the dried flower husks have long since been shorn.—R. H.

THE BEAUTY OF A MASSED BORDER OF MICHAELMAS DAISIES.
The perennial asters are unsurpassed for garden decoration in autumn.

A DOUBLE WHITE DELPHINIUM

SIR,—Some years ago I started with the fascinating hobby of raising delphiniums. The improvements noted from year to year were remarkable, but for a long time the much sought after white double delphiniums refused to make their appearance. Last season however, they appeared and they are even much finer than I had expected, considering the white varieties existing to-day in commerce. I enclose a few pictures of the best seedlings. (1) is a lovely milky white with a large brown centre, a plant of graceful habit and strikingly decorative when planted between blue delphiniums. (2) showed only a few flowers in its first flowering season, but they were of remarkably large size and with several rows of clear white petals. (3) forms very regular white flowers with two rows of broad, flat petals. Another of similar shape is a slightly blushed white of alabaster-like beauty. There are also a few seedlings with dark metallic buds, which, on opening, are a delicately whitish blue mauve. The individual flower pictures are exact natural size.—P. WILHELM.

A FLOWER OF REMARKABLE SIZE WITH SEVERAL ROWS OF CLEAR WHITE PETALS.

THREE TYPES OF NEW SEEDLINGS OF DOUBLE WHITE DELPHINIUMS.

ROSES IN BLEAK AND POOR SITUATIONS.

SIR,—With so many new houses being built, and therefore gardens being made—and what is a garden without roses?—I feel that my experiences of the last two years may be helpful to others whose gardens, or gardens to be, are similarly situated. My own garden is 1,000ft. above sea level in a sandstone district, the surrounding country being hard and wild with no trees growing except in the valleys, and we are fully exposed to all gales except from the east. I have a clump of cerastium planted on a slope which is growing up the slope owing to these winds. A still day is rarely experienced. The soil is one spit of poor sandy loam and then gravel, and yet I have had a wonderful time with roses, having had roses since the second week in June, and am still cutting (October 16th). All gardeners do not live in favoured districts, and it seems to me that too little is written in the gardening Press for people who have conditions similar to my own to contend with and who have to fight for every bloom they get. How often is one told to take cuttings of this, that and the other "now they have finished flowering" when the things are only just showing bud. And when one thinks of the number of people who, having no experience, follow the advice given to the letter, with poor results and so get into the frame of mind which says "You can't get anything to grow in this district," one is forced to the conclusion that all writers of seasonal instructions should specify South, Midlands, etc. At

Digitized by Google

certain seasons of the year I and my friends work three to four weeks behind the times given in the standard works.

To return to roses. When this house was to be built I had all the turf stripped off and stacked from the land actually covered by the building, and then twelve months after, when preparing my rose-beds, I took out all the soil and gravel to a depth of 2ft. and filled up with the turf (chopped up, of course) and cow manure to within 4ins. of the level required, some of the fine soil being replaced as being absolutely necessary to satisfactory planting. My roses are thus literally grown in the fat of the land. Another point. When cutting, cut with long stems to a good fat eye and be rewarded with a good strong shoot which soon flowers.

There is good and bad in most things, and the good in a situation like this is that I never have to use a syringe (indeed, I have not got one), disease being non-existent and green fly easily dealt with by the finger and thumb.—A. H., *Halifax*.

TRELLIS AND HOW TO MAKE IT

THERE are several forms of trellis in ordinary use. Ordinary expanding trellis is shown at Fig. 1, interlaced diamond at Fig. 2, ordinary square at Fig. 3 and interlaced square at Fig. 4. The expanding form shown at Fig. 1 is sold in widths

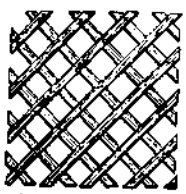


FIG. 1.

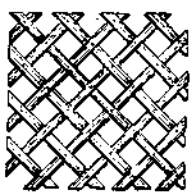

FIG. 2.

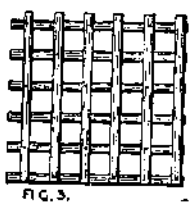

FIG. 3.

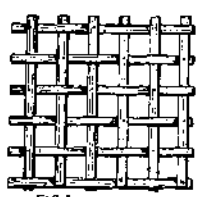

FIG. 4.

of 1ft. 2ft. and up to 6ft., opening out to 12ft. For use with the trellis, grooved top and bottom boards and posts grooved on both sides are obtainable. With the necessary material, usually about 1in. by ¼in., trellis is easily made as shown at Fig. 5. The spacing, which is generally 3ins., is effected by means of a grooved block of 1in. wood, 3ins. wide and about 18ins. long, as at Fig. 5A. The nails should be ¾in. long, driven right through the wood and then hammered over on the other side, with the nail head placed on an iron block or flat iron.

Unless trellis is well supported it is very liable to damage, and when used for fences, posts should be erected at every 3ft. with stout cross rails. An example of a simple trellis fencing is shown at Fig. 6. The upright posts are 2ins. by 2ins. and the rails 2ins. by 1in., preferably 1½ins. The rails are let into the upright posts so that the front surfaces are flush, the trellis being then nailed on direct. A much stronger form of fencing is shown at Fig. 7. The posts should be 2½ins. by 2½ins., the rails 2ins. by 1in., let in on both sides, and then the trellis, which is firmly held by the rails, is capped by a grooved top railing as indicated in section.

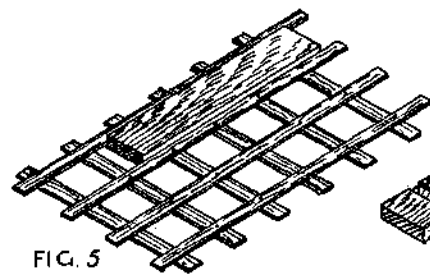

FIG. 5.

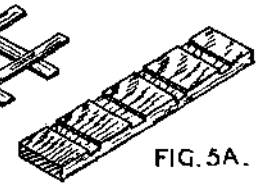

FIG. 5A.

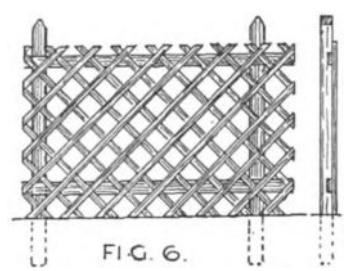

FIG. 6.

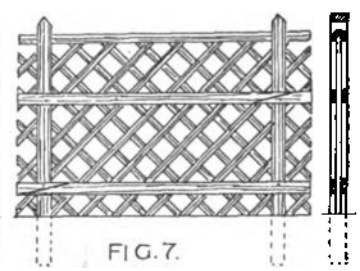

FIG. 7.

When trellis is used to increase the height of existing fences, it is advisable to use the material as panels with some square trellis in between, as shown at Fig. 8. The large panels should be about 6ft. by 3ft. and the small panels about 2ft. This kind of fencing can be built with stock material with very little difficulty, and looks much more effective than plain lengths of the expanding trellis nailed to uprights and rails. The square trellis shown at Fig. 9 is quite effective when arranged as a fence or division between one part of the garden and another. The meshes should be about 4ins. with 1in. by ¼in. material, but a larger mesh can be arranged if stouter material is used.

The various joints required in securing the rails to the posts are shown at Fig. 10, A indicating an upright post. The method used in fitting the grooved top rail is shown at B, the narrow strip at C being a fillet to support the edges of the trellis instead of using a grooved upright. The capping shown at D forms a neat finish to the uprights, the latter being cut at the top as at E. Rails are let in as at F, the groove being ¼in. deep, as at G. The method of joining lengths of railing is shown at H. The strip at J is used when the trellis is nailed to the inside of the rails to form panels. A method of using capping is shown in the section at K; L represents the rail and M the trellis.

Trellis work to be attached directly to the house for training roses should be made on a framework, as at Fig. 11. The framing should be joined at the corners with the lapped halving joint, as at Fig. 12, and then attached to the wall by holdfasts. The trellis is nailed on to the framing after it is fixed to the wall. Trellis fitted in this way can be removed with very little trouble. An alternative form of trellis for walls is shown at Fig. 13. It can be made on a separate framework or attached to uprights.

New wood should be coated with a preservative. Creosote is in common use, but there are several proprietory preservatives which are equally good and obtainable in colours. Paint can be used, but it will be found somewhat expensive and it is doubtful if it is as effective as a good stain.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Each must be sent in on a separate sheet and must not be more than 300 words in length.

THE HALF GUINEA HINT.

Planting Rose Trees.

Now that the season for planting is at hand, I wish to suggest a point frequently overlooked, that is, the importance of letting the roots rest on a firm surface which, after being well dug or stirred, should be trodden thoroughly. Most people tread the surface when the tree is planted, but forget that the loose earth covering the roots, having no firm foundation, cannot be pressed closely to them, as it should be. In addition, I would say: do not plant in frosty weather; do not let any manure—even if rotten—come in contact with the roots; and do not plant too deeply, just enough to cover the collar at least 1in. but not more than 2ins. A piece of string tied round the collar with loose ends of an inch will serve as a useful guide. Lastly, make the hole sufficiently wide so that the roots can be spread out as far as possible, and your careful planting will ensure success.—A. H. C.

Training Rambler Roses.

When training rambler roses on arches I find it a good plan to stretch a piece of wire netting over the top of the arch. This should be attached to the woodwork of the arch by means of wire. It prevents the shoots from falling through the top in summer and adds much to the neatness of the arch.—W. B.

How to Make Delicious Marrow Chunks.

Four pounds of marrow, 2lbs. of sugar, ½lb. of preserved ginger, two lemons. Cut the marrow in pieces about 1½ins. square. Put on the fire in a jelly pan with just enough water to cover. Bring to the boil, then drain away water. Return the chunks to the pan with 1½ pints of water and boil ten minutes. Strain again, keeping the water. Put water on with sugar and juice of lemons to make syrup. When boiling put in chunks and ginger, cut also in squares, and boil for half an hour, or until marrow is clear. Put in wide jars and cover at once.—M. D.

Treatment of Herbaceous Perennials.

After cutting down the stems of these, the remaining portions are often left to decay, unless they are blown down by the wind. In the interval the stumps—at least those that are hollow—are filled with water, which, in the event of frost, becomes frozen, the probable result being that injury is inflicted on the crowns. Though it is not suggested that the stumps should forcibly be removed, it is an advantage to clear them off as soon as they can be parted readily from the base. The gaps left will fill with soil during rain, thus affording protection to the crowns. If severe weather is expected, they should be filled up without delay. I consider this an important item in the cultivation of border plants, and make a point never to overlook it.—MENDIP.

A Use for Black Currant Prunings.

Black currant prunings make excellent shelter for sweet peas during the winter. If the prunings are trimmed and pushed thickly into the soil around the peas they afford partial shelter against wind and frost. They also afford supports up which the peas can climb. In addition they may form strongly rooted black currant plants ready to be transplanted by the time the sweet peas are dead.—J. H. B.

Cuttings of Lithospermum.

Those who have trouble to strike Lithospermum prostratum should keep a plant in a greenhouse in a pot and take the cuttings from the plant when about 2½ins. to 3ins. long and put them in a warm house. Then they will root quite easily, and the tips from these if taken will also root without trouble. I usually strike the cuttings in plain sand all through the summer.—W. J. V.

The Winter Jasmine.

It is well worth while remembering how freely the yellow winter jasmine (J. nudiflorum) will reproduce itself by means of self-layered branches. Even if these are merely lying on the surface of the ground, they will root freely, and form nice little plants in a year or two. A well established bush is almost sure to have anything from six to twenty-four of these young plants growing round it, and they may be severed and moved to more desirable quarters.

Early this year I moved about eighteen new plants formed in this way, and I see there are now at least another half-dozen trailing shoots that have commenced to root.—B. D. S.

The Pruning of the Rambler Rose.

Great mistakes are often made when pruning rambler roses, by leaving too many old branches in the bush. Young ramblers, when planted the first season, should have all the weakest growths cut out close to the ground, and the next season several young strong growths will appear; this will enable the grower to cut out old branches left from its first season's growths. By the fourth season there will be sufficient young growths, so as to enable one to cut out all old branches and tie nothing but new branches in.

Pruning in this way, you have always got a good strong healthy rambler and large trusses of blooms. They also require liberal soakings of manure water or soap suds from the wash tub.

When training ramblers to posts or rustic archways, I always find white string the best, as tar string always seems to burn the young growths.—B. R.

Silver Leaf on Plum.

I had a plum tree very badly affected by silver-leaf, and I cut it back to within a foot of the stock, removed all soil off roots, gave it a very liberal supply of soot and mortar rubble and fresh soil on the roots. The following autumn I moved it again, giving it plenty of soot and mortar rubble, and it has not shown any sign of silver-leaf since.—H. S. B.

OUR SERVICE BUREAU

Though so many subjects are dealt with in each issue of THE GARDEN, *it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, there is always information available from a staff of expert contributors and consultants; and there is no charge for this. It is one of the additional means of service which* THE GARDEN *is glad to render to its readers.*

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope and the coupon that will always be found in each issue shall be sent with the enquiry. We would point out, however, that we cannot undertake to supply readers with plans and designs of gardens, but will willingly assist in giving suggestions for planting.

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2.*

We have selected the following enquiries, with their answers, as being of more general interest, and therefore worthy of publication.

Manure for Sweet Peas.

Can you tell me what manures to use for sweet peas and in what proportion. I cannot get horse, cow or pig manures. I thought of putting Wakeley's Hop Manure at the bottom of the trench, but I do not know what kinds to use above that, or whether the manuring should be done now or in the spring.—A. J., Thornton Heath.

Wakeley's Hop Manure would be excellent mixed with the soil from 6ins. below the surface to a depth of 18ins., during the time that the trenches are being prepared for the next year's crop. While the soil is in a fairly dry state this autumn is the best time to do this work. Six ounces of basic slag per square yard should also be forked into the top 12ins. of soil. Next year, when the plants are about 4ins. to 9ins. and growing freely, apply 2 oz. of superphosphate of lime per yard run of row during showery weather, and repeat this operation one month later. Keep the stimulant off the plants.

Wintering Chrysanthemums in a Cold House.

I have a collection of seventy Japanese and incurved chrysanthemums, but my greenhouse has been dismantled of its heating apparatus by a former tenant. So I am now faced with the problem of heating it or losing my plants. I intend leaving this house next year, consequently I do not wish to instal an expensive heating apparatus. I have a good oil stove used for heating bedrooms, and shall be grateful if you will advise me if this will be suitable for greenhouse or if I must procure some other apparatus. I have a dozen plants of Salvia Harbinger, and shall be glad if you will advise me how to treat them to enable me to get a good supply of plants for spring.—T. P. S., Leicester.

If the chrysanthemum pots are well packed in old newspapers and mats are placed over the suckers growing in the pots, you can winter them without any artificial heat in the greenhouse. Of course, the mats must only be put on while frost prevails. In early spring root cuttings—about February 20th.

The salvias you will have difficulty with; damp is their enemy as well as frost. The

CLEAN CROPS ARE GOOD CROPS

Those dog-in-the-manger trees

YOU really can't afford them. Fruit trees that don't bear take too much room, and keep light and air from other crops.

Yet this dead loss can be turned into a highly profitable crop by quite unusual cleanliness.

That merely means a thorough cleansing of the tree when it is dormant. This season, trees treated with CARBO last winter have been bent down with fruit, where unsprayed trees have failed completely.

Now is the time to destroy moss, lichens, hibernating insects. Kill the eggs of Aphis, Apple Sucker and Caterpillar. Save next season's fruit crop. CARBO is put up in convenient quantities for the smallest garden as well as the largest. Get CARBO now. It costs so little to spray with this supreme winter wash—and saves so much.

oil stove, properly managed, would help considerably. A great deal depends on weather conditions. You can, however, raise the salvias from seed sown in February. The plants resulting would flower from July onwards. Cuttings are rooted in spring, not in the winter.

A Magnolia which Rarely Flowers.

I have a magnolia on the front wall of my house which has been planted twenty years, but rarely has any flowers. It appears quite healthy, and is about 15ft. high. The wall faces south. I should be glad if you can suggest something to induce it to flower. I have given it occasional applications of fertilisers, without effect. It has never had more than three flowers in a season—the last two years not any. This town it about eighty miles north of London. Is it necessary or desirable to protect it with matting during the winter?—E. M., Peterborough.

We should think that, in order to bring your magnolia into flower, it might be advisable to give a light pruning, and so bring the stem portion into balance with the root system. A good part of any old and dead wood which is on the bush should be removed, also some of the new wood should be shortened. At the same time it might be desirable to dig up the soil round the roots and find out if anything is attacking the plant there. Ease up the soil around the plants and slightly shorten one or two of the longer roots, which will stimulate the growth of a more fibrous root system.

If the winters are very severe it might be advisable to cover the plant with sacking; but, at the same time, as it is planted on a south wall, we should think that this would be unnecessary.

How to Rid the Soil of Wireworm.

Could you advise me how to get rid of wireworms in a flower bed. We are very bothered with them.—K. W., Oltey.

The most effective method of ridding the soil of wireworms is by trapping the pest, or by dressing the ground with a soil fumigant. The wireworms can be trapped by means of pieces of potato, carrot or turnip. Push a pointed stick into the bed and then bury the traps 3ins. in the soil. Examine the traps daily. A material known as "Vaporite" is an excellent soil fumigant. Directions for its application are given with the material. Sprinkling soot over the surface and lightly forking it in is also helpful.

Plants for a Woodland Garden.

I am adding to my garden by taking in part of an adjoining wood. This wood consists of overgrown copsewood, being chiefly large stools of edible chestnut and ash, the sticks of which are 20ft. to 40ft. high, with a tree here and there, left at previous cuttings, 9in. to 12ins. diameter. There are also some nice holly bushes 10ft. to 15ft. high, and the ground is full of bluebells, wood anemones and a few primroses. The soil is very dry, fine, hungry yellow sand, 12ft. to 14ft. deep, overlying strong yellow clay.

I am proposing to convert this piece of land, which is some third of an acre in extent, into a semi-wild woodland garden, and with this view I am cutting down the copsewood, but leaving the best-shaped and largest sticks, irregularly spaced about 12ft. apart, to grow into timber, and also, of course, leaving the hollies. And then, from time to time, as opportunity offers, I propose thinly planting the ground with suitable flowers and flowering shrubs or, possibly, sowing flower seeds.

If any advice or useful hints could be given as to the best methods to pursue and the most suitable plants to use in carrying out these proposals, I should be greatly obliged.—A. W., Canterbury.

Twelve feet apart is close to leave the sweet chestnut stick to grow for timber. As they grow it will be necessary to reduce the number considerably, or they will entirely cover the ground in a few years.

As primroses grow freely, plant also liberally polyanthus and Primula japonica varieties.

Daffodils, snowdrops, chionodoxas, eranthis and the larger Spanish bluebells would be useful bulbs to plant. Also try Liliums giganteum, Martagon and pyrenaicum and colchicums.

Scatter about seeds of foxgloves, Œnothera biennis, verbascums, Epilobium angustifolium, Lythrum salicaria, Calendula officinalis, larkspurs, Lychnis coronaria and honesty.

Perennials to naturalise include lythrum, epilobium, Saxifraga cordifolia, S. umbrosa, Solomon's Seal, lily of the valley and Michaelmas daisies.

Among shrubs the following are worth trying: Berberis vulgaris and some of the hybrids which are readily raised from seed, Spiræa japonica, Symphoricarpus racemosus, Kerria japonica and the double variety flore pleno, Cotoneaster frigida, Berberis (Mahonia) Aquifolium and Hypericum calycinum.

Gumming in Peach Trees.

I have a peach tree, Faranti et Moira, planted in 1921, fruiting for the first time this year, and now showing lots of vigorous and young branches. It has developed resin in the stem and bark, not too terribly. Is it the beginning of the end? If not, what can I do and when?—L. Y., Oporto.

No doubt the disease known as "gumming" has set in on the young peach trees. Although this is not the easiest of trouble to combat, we do not think it means the end of the tree. In the first place, it will be best to cut away those branches showing the "gumming" on the bark, and to paint such branches as are left with lead paint. Then we advise lifting the tree and root pruning in November. Cut back the coarse, lateral and downward striking roots to little more than half their original length. Then replant, but the border should be attended to also. Cold, wet soil, undrained, or soil that lacks lime, predisposes the tree to this trouble. See that the drainage is well-nigh perfect and work in plenty of broken mortar rubble. If possible, take out some of the old soil and replace it with fresh loam. No manure should be added, though applications of bone meal or basic slag will do good. The lifting and pruning should check growth and the renovating of the border should result in the tree making short, healthy growths that will escape "gumming."

"THE GARDEN" CROSSWORD

THE CHRYSANTHEMUM SHOW

THE great popularity of the "golden flower" continues unabated. There was a queue of members and visitors waiting outside the Royal Horticultural Hall, Westminster, on the opening day of the Annual Show of the National Chrysanthemum Society, and quite early in the afternoon it required considerable perseverance to go round the exhibits, so dense was the throng of interested persons.

We would suggest to the executive of this special flower society that they would do well to enforce the R.H.S. rule prohibiting smoking in the hall. Unfortunately, of late, the tendency seems to be to countenance smoking in the hall on the occasion of these special shows, over which the R.H.S. has no control. We are not alone in considering this to be a great mistake and not in the best interests of the societies. At one time, during the early afternoon of the first day of this magnificent chrysanthemum show, there was an appreciable haze of smoke hanging over the flowers, thus destroying part of the first impressions of the general effect which, otherwise, was wholly admirable. Even in the present year of grace there is a considerable number who dislike tobacco smoke, and we met several such, considerable patrons of horticulture, who shortened their intended stay solely on account of the smoking.

The regular visitor to flower shows at the R.H.S. Hall usually first inspects the newest sorts, and on the present occasion there was a fair variety awaiting attention. During the morning the society's Floral Committee had sat in judgment on a great many new varieties and awarded ten first-class certificates. To the lover of grace and beauty in flowers the variety Fifi stood out above all the others, and yet it was the smallest of all the new ones. It was seen at its best in the most charming group arranged by Messrs. Cragg, Harrison and Cragg. They have raised many delightful chrysanthemums of most types—we do not, at the moment, recall any of the large exhibition Japanese—but none, to our mind, more charming than this real pink variety which makes such graceful sprays.

We have brought away from the Chrysanthemum Show special memories of four varieties. These are Fifi, just mentioned; Mrs. R. Harris, a large rich yellow single of great beauty, in the magnificent "Display of Singles" so well arranged by Mr. F. J. Yarrow's gardener; West Hall Gem, another single, but with rather broader florets of exquisite colouring which at one moment seemed to be a rosy terra cotta and the next appeared to be a rosy fawn with a suggestion of buff apricot. This fascinating variety was shown with eight other splendid vases of singles by Mr. F. C. Stoop. The fourth is an anemone-centred single in the excellent collection of Messrs. Keith Luxford and Co. At present it is an unnamed seedling. The attractive cushion of central florets is tipped with gold and surrounded by long, flattish, bright crimson florets. The colouring is very uncommon in this type of chrysanthemum and if only it can be fixed in a flower with fuller ray florets it should be very valuable.

While the above are the varieties which most impressed us, they by no means exhaust the beauties of the Show. Mr. H. J. Jones set up another of his magnificent collections which won him the large gold medal. His tall stands of specimen blooms, pricked out with green leaves of the sweet chestnut at each stand, separated by a perfectly grown plant of the graceful fern-like Acacia robusta were magnificent. Along the front he had gilt baskets containing delightful colour schemes. Mona Davis and James Baxter, an association of mauve and wine crimson; A. B. Hudd, a medium-sized Japanese variety of crimson colouring, blended well with the single yellow variety Mrs. R. F. Felton; Primrose Poiteau, with the thread-like florets of Pink Tokio and an occasional blush-coloured pompon variety were even more charming; while several shades of pink made another desirable basket.

Lady McNaughten sent from Sandhurst Lodge, Berks, some exceptionally well grown plants of Jean Pattison, Phyllis Cooper, Susan and other varieties which made a handsome group. These monsters were single plants and, we understand, were not quite a year old. Another exhibit, which departed from the general, was the interesting collection of pompon varieties staged by Mr. J. W. Hussey of Exeter. It made an attractive display, and among the many varieties there was a vase of Baby, the tiniest chrysanthemum imaginable.

Twenty-five or so years ago Mr. W. Beckett, gardener to the Hon. Sir John Ward, who had been a noted exhibitor of chrysanthemums for a number of years, ceased to exhibit. This year Sir John wished him to test his skill again with the result that he won a number of first prizes with superb collections of exhibition blooms. Viscount Hambledon, Lady Annaly, Colonel Brassey and Mr. R. L. V. Sherwood were also very successful exhibitors.

The various decorative classes added much to the general effect of the Show, but it was freely commented upon that the most successful arrangements were those with the monster blooms and autumn foliage. It may be that these take the judge's eye best, but it would have been thought that the decorators possessed the skill to make pretty vases with the singles and the smaller Japanese blooms.

New Chrysanthemums.

AQUITANIA.—A large, rounded Japanese variety which, no doubt, will be greatly valued by exhibitors. The rolled florets intercross gracefully, much in the same manner as in the best cactus dahlias. The colour is a bright chestnut and the gold reverse shows at the tips. First-class certificate to Mr. H. Woolman.

CARINTHIA.—An incurving Japanese variety of the best exhibition type. The broad light chestnut florets show much of their golden reverse. First-class certificate to Mr. H. Woolman.

EVERLASTING.—We admired the substantial merits of this medium sized, rounded single last year, when it was first shown. The ray florets are much, velvety crimson colour. There is a narrow yellow zone and the flowers have small discs. First-class certificate to Messrs. Keith Luxford and Co.

FIFI.—This is a most charming little Japanese variety of real bright pink colour. It makes decorative sprays of bloom and the raisers say it is very easy to grow. First-class certificate to Messrs. Cragg, Harrison and Cragg.

IOLANTHA.—Several large vases, illustrated the value of this medium sized Japanese variety, which is of soft pink colour. First-class certificate to Messrs. Cragg, Harrison and Cragg.

LADY FINLAY.—This is a particularly good white Japanese variety, said to be a seedling from Queen Mary, but it has narrower florets and more graceful habit, while being equally large. First-class certificate to Lady Finlay, Warfield Grove, Berks.

MISS MARY POWELL.—A medium sized single of rounded form and yellow colour, freely stippled with terra cotta. First class certificate to Mr. H. Woolman.

MRS. M. DUNKELS.—A large Japanese variety with broad drooping florets of dark plum purple. First-class certificate to Lady Finlay.

THALIA.—An exhibition Japanese variety with broad florets of rich chestnut colour showing an old gold reverse. First-class certificate to Messrs. Keith Luxford and Co.

YELLOW MAJESTIC.—This is a pale yellow counterpart of the well known large exhibition variety.—First-class certificate to Mr. H. Woolman.

FLUE DUST FOR FLOWER BORDERS.

HAVE you ever thought of making use of flue dust for your flower borders? If not, I would strongly urge it being done as flue dust proves a material of extreme value alike for existing flower borders and those which are in course of preparation.

Flue dust as sold is generally available in two distinct forms, *i.e.*, the fresh variety which has only been a day or two out of the flues, and the old aired variety which has been exposed to the influence of the atmosphere, but not to the action of rain, for a varying period, generally not less than a month in duration.

As goes without saying, the fresh variety is far and away more active than the older aired form. Sometimes it proves too active to be forked into the borders close to the roots of established subjects on account of the poisonous cyanogen and other similar compounds which are present. The aired form, however, has to a very great extention these somewhat dangerous chemicals, either by oxidation or by a simple process of evaporation, and it may be recommended, therefore as being the better of the two for established borders, while the fresh flue dust is undoubtedly miles ahead of the other for use when the sites are being prepared.

The colour of the two samples is as a rule very similar, but the aired variety has less odour and at times has been shown to be rather less soluble in water. The exact composition of any particular sample of either kind of flue dust can only obviously be obtained by submitting it to analysis and on account of the expense of this operation I do not recommend it.

The fresh flue dust is the most valuable for freeing the soil from different undesirable forms of insect life, but even very old flue dust has a markedly deterrent action, and this can safely be enhanced by mixing it with from 5 to 10 per cent. of crude naphthalene, obtainable as a rule very easily from gas works or coke oven companies.

Both forms of flue dust contain substantial quantities of potash, and this proves a most valuable fertiliser for our flowers. Where flue dust is employed either as an autumn dressing to established borders or in the preparation of new ones, it is unnecessary to apply any kainit or other potash containing stimulants, as is generally done. One can also save any wood-ashes which would otherwise be used, and employ these in other ways.

Old flue dust can be mixed with a variety of other slow-acting fertilisers for application to flower borders in the autumn. Bone meal is a common addition, the proportions being two parts dust to one of the meal. Basic or reverted superphosphate can also be added, good proportions being three parts dust to a single part of the basic or reverted fertiliser. Horn dust can also be added, but on account of its bulky nature one part of it will be quite sufficient to mixing with nine or ten parts of flue dust, while leather dust, which is also valuable for flower growing, can be mixed with it in similar proportions. The best rate of application is about a handful of flue dust per square yard.

OBITUARY

Mr. WILLIAM SPINKS.

WE regret to announce the death of Mr. William Spinks, who for some considerable time was in charge of the landscape department of Messrs. Hewitt's, Solihull, Birmingham.

Mr. Spinks was born in 1844 and may be rightly called one of the "old school" of horticulturists. His original training was at a nursery in the eastern counties, from where he moved to the R.H.S. gardens at Chiswick, where he was successful in obtaining the Chiswick Certificate. From there he moved to Chantilly, where he was given an appointment under the Duc d'Aumale—this was about 1870. Having gained a wide knowledge of horticulture, he took the position of Superintendent of Aston Lower Grounds (Birmingham), under the control of Mr. Quilter. From there he was engaged as manager of Hans Niemans' nurseries at Harborne Road, Edgbaston, which soon after became controlled by Hewitt and Co., Solihull. He laid the foundation of the present firm's garden architecture department and took an active part in the firm's business up to about five years ago, when, on account of his great age, he was forced to relinquish his duties.

PUBLICATIONS RECEIVED.

"Aims and Methods in the Study of Vegetation," edited by A. G. Tansley and T. F. Chipp. Published by the British Empire Vegetation Committee and Crown Agents for the Colonies, price 12s. 6d. A most interesting handbook intended for all practical workers throughout the Empire. In its pages can be found accounts of methods of investigating natural vegetation both scientifically and practically. The volume is largely the outcome of proposals put forward at the Imperial Botanical Conference in 1924. Many gardeners and, indeed, those who are at all interested in the economic aspects of botany and horticulture, will find the book both valuable as a work of reference and instructive.

"Beautiful Flowers and How to Grow Them," by Horace J. Wright and Horace P. Wright. T. C. and E. C. Jack, price 10s. 6d. This is a new and revised edition of this excellent amateur gardeners' guide to flower culture. It is comprehensive in its scope, dealing with greenhouse subjects as well as all hardy plants. The chapter on flowers for the suburban garden all keen amateurs will find of considerable assistance when they come to the selection of plants for the furnishing of their suburban garden. The whole book is written simply and clearly and well illustrated by numerous well executed colour plates and line drawings, these latter to illustrate practical points. That there has been the necessity for a new and revised edition speaks well for the popularity of this book, and this present edition bids fair to outstrip its predecessor, since it is, if anything, more helpful to the man who gardens himself and in a small way.

WAKELEY'S *Celebrated* Hop Manure

(PATENTED)

THE ORIGINAL AND ONLY RELIABLE SUBSTITUTE FOR STABLE MANURE

DIPLOMA AND MEDAL, ROYAL INTERNATIONAL HORTICULTURAL EXHIBITION, 1912

DO YOU REALISE IT?

A large bag of WAKELEY'S PATENTED HOP MANURE at a cost of only 7/- carriage paid to your door (if within 25 miles radius of London, or at a trifling extra if beyond), GOES AS FAR AS A CART-LOAD OF STABLE MANURE, without any of the defects of the latter; gives better results, is easy and clean to use.

Every ounce of Wakeley's Hop Manure is of value to the soil, supplying the necessary HUMUS in addition to the valuable plant food. Worthless rubbish is not added to make weight (as is the case of some artificial manures advertised).

Thousands do realise it, the proof of this is the constant flow of UNSOLICITED LETTERS received from time to time in praise of the wonderful results obtained at such a moderate cost (see Booklet for selection).

BEWARE OF IMITATIONS.—Genuine Only in our Marked Bags containing Guaranteed Analysis.

Just a post card, and our Catalogue of Bulbs and Garden Sundries at carriage paid prices will be sent free.

CASH PRICES (including bags):

Small (about 1 bushel)	3/-
Large (about 4 bushels)	7/-
5 Large	33/9
10 Large	65/-
20 Large	120/-

Carriage paid by Pickford's or to any station within 25 miles of London, including delivery if within free delivery radius of Railway Company; 6d. per bag extra for every 50 miles or part beyond. Maximum extra charge Great Britain, 2/6 per bag.

NEW HARDY CRIMSON BROOM

AT Chelsea Show (1925) the King said "That red Broom is certainly very striking." This was the new crimson Broom "Dorothy Walpole," which received the unanimous Award of Merit from the R.H.S. as well as other distinctions in London and on the Continent. Plants have been sent to U.S.A., Canada, Australia, New Zealand, France, Holland, etc.

In the Field, *a well known ex-Curator of Kew Gardens wrote: "The richest coloured Broom known is one named 'Dorothy Walpole.' It is as hardy as the common Broom . . . and is very free-flowering . . . the colour is rich velvety crimson . . . more attractive than any of the coloured Brooms yet seen." The colour far surpasses Cytisus Dallimorei, and the growth is as vigorous as C. Andreanus; it requires no special treatment nor any kind of protection whatever—just a hardy shrub for ordinary garden soil in any part of the British Isles, however far north.*

A Vice-Chairman, Floral Committee, R.H.S., wrote: "Everyone who has seen my plant has been astonished at its warm glowing red"; and from a lady in Devon: "I am so delighted with the Broom 'Dorothy Walpole.' It has done splendidly and is like a sparkling gem in the garden—one mass of flower."

NEW SEASON'S PRICES.

Strong pot-grown plants now ready for planting out, to flower in May, 7/6 each. Carriage paid rates to any station in Great Britain or Ireland: One plant, carriage paid, 10/-; two plants, carriage paid, 18/6; three plants, carriage paid, 26/-; six plants, carriage paid, 49/6; twelve plants, carriage paid, 99/-.

THE GARDEN

VOL. XC.—No. 2868. NOVEMBER 20, 1926. PRICE TWOPENCE.

NOTES OF THE WEEK.

The Arrival of Plants.

A READER has told us his experience of ordering a number of plants from two different firms. The one sent no acknowledgment of his order. He heard nothing further until one morning half an hour after he had left for work the plants were dumped on his doorstep by the railway company. The other sent a postcard on the day of despatch announcing that the plants had been sent off with a little note added of instruction what to do if the plants could not be planted at once owing to inclement weather or other causes. It is needless to say with which of these two firms our reader is more pleased. One showed itself to be helpful—and also a good business concern; the other did not. However, the reason for this note is not to discuss business qualifications but to impress on readers that they should make arrangements for the reception of plants in case of their absence. More often than not plants will arrive when it is impossible to deal with them at once. They may have been several days on rail, or the temperature may be below freezing. At any rate it is important that they are taken care of at once lest they come to harm. Many cases occur every year of valuable plants being left in their wrappers a week or more after their arrival, and then the nurseryman or the soil or the weather is blamed if they do not succeed. Suggestions have been made in these pages during the last few weeks on how to deal with plants on their arrival. It is the duty of every gardener to see that these are carried out without delay.

Our Post Bag.

THE Editorial staff of THE GARDEN has been amazed at the many spontaneous letters of appreciation that reach us every day. Our post bag has increased by leaps and bounds, and almost every letter, on whatever subject it may be written, includes a sentence that shows how much readers appreciate THE GARDEN. There can be nothing so interesting as our post bag. We get letters on every conceivable gardening subject, even on matters so far afield as moss on thatch and the best varieties of gold fish for a small lily pond. These letters are not only interesting in themselves, but also because they show how widely spread are the ramifications of gardening. Each week we try to give as much space as possible to correspondence, but even then it is far short of the space that would be filled if we printed all the letters received. We hope that such readers as do not see their interesting epistles printed in our correspondence columns will realise that we have to choose material that is of interest to the greatest number of our readers. Large though our post bag is, we would welcome still more letters, for this is the best way of creating that close co-operation so necessary between readers and paper.

An Enquiry.

SEVERAL readers have asked us our opinion as to how much ground one man can cultivate successfully working in the evenings when there is sufficient light and at week-ends. This has been a difficult question to answer, as, of course, it depends on local conditions. Soil is an important factor, for a man can dig a much larger area if it is light and sandy than in a heavy clay. Most important of all is the class of garden. If the owner is an enthusiast over herbaceous plants, perhaps a considerable portion of the area under cultivation will be laid out in beds and borders, a form of gardening that takes up a great deal of time if it is to be satisfactory. But, given an ordinary garden where a fair proportion of vegetables and fruit is grown, and the rest is given over to the cultivation of flowers—which may be called an average garden—how much can be cultivated by one man in his spare time? Will readers tell us their experience?

HAVE YOU

¶ *Overhauled your rockery? All decaying leaves should be removed, the surface soil lightly stirred and any exposed roots covered with a top-dressing of prepared compost.*

¶ *Examined the cuttings of your violas, pansies, antirrhinums, etc., which are in frames? Keep them well ventilated and prevent damping.*

¶ *Pruned your greenhouse climbers, such as Plumbago capensis (leadwort)?*

¶ *Trimmed your hedges of hornbeam, beech or privet?*

¶ *Examined and, if necessary, renewed the stakes of your standard roses, shrubs and fruit trees?*

¶ *Taken cuttings of gooseberries and currants?*

¶ *Lifted and stored in the same way as beetroot your scorzonera and salsify?*

In Praise of Single Roses.

ROSES which are single possess a charm and grace of their own. They have already a host of admirers, and as each year goes by they are grown in even greater numbers. There are single hybrid tea roses suitable for bedding, single climbers for post and pillar, and rose species which produce beautiful single blooms in great profusion when left to themselves in the wild garden or hedgerow. These roses need no special attention; they should be planted, pruned and fed with the same care as other roses.

Hybrid tea varieties which are single look most effective when massed in beds by themselves. On our front cover a few of the best of the bedding varieties are illustrated. At the top of the picture towards the right is Isobel, a carmine red variety flushed with orange scarlet, which grows freely and produces its blooms continuously. On the extreme right is Red Letter Day, a glowing scarlet crimson semi-double variety. It is one of the most decorative of bedding roses. The pure white rose in the centre of the picture is Innocence, a most beautiful single rose, with large blooms and attractive clusters of deep yellow stamens. Its growth is strong and upright and its foliage mildew-proof. Vanity is the rose pink semi-single variety at the bottom left-hand corner. This is one of the hybrid musk roses, and, although suitable for bedding, it is more effective when grown as a large bush. The scarlet variety at the top of the picture is Allen Chandler, a climbing hybrid tea, which is an excellent pillar rose. The large-flowered rose with pale sulphur petals and deep amber stamens is Mermaid, another climbing variety. It is one of the most attractive varieties of its class, and it flowers for many weeks when grown on a wall or trellis.

There are numerous other fine single varieties, such as Irish Elegance, Irish Fireflame, Mrs. Oakley Fisher, Vesuvius, and Dainty Bess (a new salmon pink rose with pretty crinkled petals), as well as such species as Moyesii and hugonis. Some of these should be planted in every rose garden.

Digitized by Google

THE SHRUB GARDEN

This is the time of year when the selection and planting of flowering shrubs is of immediate interest. Their ease of cultivation makes them economical for everyone, while their beauty makes them as valuable in a small garden as in a large one.

THE SHRUBBY SPIRÆAS.

IN most gardens the spiræas find a place in beds and borders of mixed shrubs, with an occasional lawn bed of half-a-dozen or more plants of one variety and a single specimen or two. A representative selection of a dozen distinct spiræas is sufficient in itself to make a most distinct and interesting border, or large bed. They range in height from about 1ft. in the case of S. bullata to about 20ft. to 25ft. in height in S. Lindleyana, which varies according to the method of pruning. Very few families of hardy shrubs provide such a long flowering season, in this case eight months—beginning with S. Thunbergii in February or early March—with an abundance of blossoms throughout the spring and summer, concluding in September and October with, among others, S. Menziesii var. triumphans and S. japonica var. Anthony Waterer. Except for one with pale yellow blossoms, S. acutifolia, the spring-flowering spiræas have white blossoms, but in summer and autumn varying shades of pink, rose, purple and red, with several good white-flowered kinds, provide ample variety of colour.

SPIRÆA LINDLEYANA MAKES A MOST DECORATIVE BORDER SHRUB.

Positions for Planting.

Spiræas are fitted for many positions in the garden, either in a shrubby border or bed. Though we often meet with them growing in half shade and sheltered positions, they are essentially sun-loving shrubs.

The plants really require no great consideration as regards soil, but before beginning to plant it is advisable to trench the ground 2ft. deep, adding plenty of well decayed manure and heavy pasture loam if the ground is light. Spiræas generally are lovers of a moist root run, which means that the ideal soil is a deep, well cultivated and moderately heavy moist loam. On light soils and in dry positions mulchings of decayed manure and decomposed garden refuse are very beneficial applied during early summer. Bone meal is a useful manure to sprinkle over the ground and fork in when cleaning the surface soil among the spiræas in late winter.

Pruning.

In considering this phase of spiræa culture we find that the plants almost divide themselves into two distinct groups, requiring different treatment, namely those which blossom in spring on the growths of the previous year, and those which flower in summer and autumn on the new shoots of the season. No definite system of pruning is required by the spring-flowering spiræas, but each year, when the blossoms fade in May or early June, as the case may be, look over the bushes and if crowded with branches, thin them by removing portions of old worn out branches, or any very weak wood, and shorten extra long shoots, if the bushes require shaping. The summer and autumn flowering spiræas are the section which benefit by regular pruning, in fact, when this work is left undone, their full beauty is never seen. February is a good time for pruning. In the case of the group represented by S. salicifolia, begin by cutting out old worn out shoots down to the ground or back to vigorous young growths, remove all weak wood and shorten the strong young shoots to about half their length. S. Lindleyana and its allies require somewhat similar pruning, though as they form very large bushes the actual cutting differs in detail. The essential points are to discard old worn-out and thin wood to encourage vigorous, healthy growths.

A Good Dozen.

A good dozen forming a representative selection is as follows: given approximately in the order of flowering, providing a season of blooming from late February until early October. To include S. Thunbergii, growing 3ft. to 5ft. high and producing small white flowers in February and March, I have made it a baker's dozen. S. arguta, white, 5ft. to 8ft.; S. prunifolia var. flore pleno, double white, 6ft. to 8ft.; S. Van Houttei, white, 3ft. to 6ft.; S. Veitchii, white, 9ft. to 12ft.; S. bracteata, white, 4ft. to 8ft.; S. canescens, white, 6ft. to 8ft.; S. ariæfolia, creamy white, 8ft. to 12ft.; S. salicifolia var. paniculata, white, 3ft. to 6ft.; S. japonica var. Anthony Waterer, red, 2ft. to 2½ft.; S. Lindleyana, white, 12ft. to 20ft.; S. Margaritæ, pink, 3ft. to 5ft.; S. Menziesii var. triumphans, purplish rose, 5ft. to 6ft. For large gardens increase the selected dozen to twenty with S. Henryi, S. Douglasii, S. bella, S. japonica var. Bumalda, S. brachybotrys, S. bullata and S. japonica var. glabrata. The heights given are only approximate, so much depends on the amount of pruning. A. O.

TREES AND SHRUBS FOR THE SEASIDE GARDEN.

IN the garden near the sea the most important thing is shelter from the force of the strong winds that sweep inland from the ocean. Happily there is quite a good selection of trees and shrubs which will give the needful protection, and the planter finds no difficulty in dealing with any position that he may be called upon to plant. The first thing to be done is thoroughly to prepare the site by trenching and deepening the soil. More often than not, near to the coast, the soil is shallow and inferior and it is very desirable to improve this and also to make it deeper. In making alterations it is sometimes possible to deepen the side of the garden that is most exposed or to raise a mound against the wind. When this can be done the creation of good shelter for the land as a whole is a comparatively easy task.

One may assume that a mound has been raised on the side of the land most exposed to the winds from the sea. This should have a natural, easy outline and on its outer edge it is an excellent step to plant the common gorse thickly. On the inner side a mixture of wych elm and Austrian pine (Pinus austriaca) might suitably be planted. The elms should be pruned so as to make them grow densely and as the trees develop some thinning will be needed. Of course, at the start, thick planting is essential so that the trees may give a good amount of shelter to one another. Other trees and shrubs which might be used in the formation of the protective belt will be found in the following list of species, all of which will flourish in very exposed positions, providing thay are closely planted at the start: Euonymus japonicus, Tamarix gallica (a most valuable subject for forming screens), Escallonia macrantha, phillyreas, barberries, cotoneasters, evergreen oak (Quercus Ilex), elders, the sea buckthorn (Hippophæ rhamnoides), hollies, willows, common juniper, Rosa spinosissma, R. rubiginosa and R. rugosa. In addition to the Austrian pine, P. Laricio and P. Pinaster are good subjects for any position on the coast.

Having created a belt of trees and shrubs that are able to withstand the wind many things may be planted inside it which it would otherwise be difficult, and perhaps impossible,

to grow in a seaside garden. Gardeners who have been used to living inland will be surprised at the wide variety of tender subjects which can be grown almost in any coast locality. The large body of water gives to the climate a mildness, most marked in the south and west, but also in evidence even on the east coast. In these situations hardy plants, as well, always providing that they can be sheltered from the wind, grow with a luxuriance that is rarely seen at inland stations. —L. B.

THE JOY OF MAKING A NEW GARDEN

BY GERTRUDE JEKYLL.

THE house and garden now shown are on the Hampshire coast. The house is built and there had been some kind of laying out of the ground, but which proved unsatisfactory. The present plan is its substitution. The entrance from the main road passes through a wide bank; the dotted line shows the existing foot of the bank just outside the gate; this will be much improved by a little further cutting away on both sides, as shown by the hard line. Within the gate the entrance road at present meanders up to the garage in a bad line that can have no justification; and the path to the front door has the same kind of weak, wavering character. A straight road to the garage, and a simple curve to the path leading to the house front will remedy these defects. A good lawn space in front of the house is desired, and this is now planned; the stretch of lawn being only broken by the path leading to a seat on a paved step, closely enclosed by a suitable evergreen. Had it been inland, this would have been of yew; but here it is tempting to use the green Euonymus japonicus that does so well near the sea. This path continues past the west side of the house and goes farther in the same line through the middle of the kitchen garden, so giving an unbroken vista through the whole length of the ground and increasing its apparent extent.

The hand-gate to the front is just within the double entrance gate, a little way clear of the foot of the bank that shelters the garden from the main road. It passes through clumps of shrubs to right and left which give a sense of pleasant repose and retirement. Then, on arriving at the end of the curve, the main lawn is seen on the right, and the flower border, B, and the planting next to the house on the left. There is already a bird-bath, not very well placed; this will come well standing on a square paved shallow step, notched into the flower border, and will be conveniently seen from one of the windows on the south front. For the sake of symmetry there should be a corresponding treatment in the other bed of the same paved square, and any ornament or stone vase for a plant, that, for height and general aspect, will make a suitable fellow to the bird-bath.

Planting Round the House.

The planting in A, all round the house, should be mainly of small bushy evergreens, rosemary and lavender, with China roses between. It would look well to have a Fuchsia Riccartoni trained up on each side of the door, and perhaps a myrtle on the west wall. Something solid, such as laurustinus or box, is to be advised at the angles, as these dense bushes serve to stop the wind that always seems to try to rush in cold blasts round the outer walls of a house. A clematis montana would cover the whole of the eastern wall and would probably return round the angles. If a continuous hedge is required along the eastern side it could well be all of Euonymus japonicus, rising to something higher, such as guelder rose and ribes, where it meets the end of the flower border E I. At any rate, there should be a good group of guelder rose or of something solid, like holly, at the end of E I, to screen off the rubbish place.

Shrubs for General Garden Purposes.

There is no more useful shrub than the common tamarisk (Tamarix gallica) that does so well anywhere near the sea, and it is a lovely thing both in flower and foliage. Atriplex Halimus is another good sea shrub, silvery grey, more or less evergreen. The hardy fuchsias, F. gracilis and F. Riccartoni, can be used freely. Veronica Traversii, should be largely planted, also sea buckthorn (hippophæ). Escallonia macrantha is invaluable, also Olearia Haastii, and Aucuba japonica will also stand well. These evergreens, with the always useful Euonymus japonicus, should form the main plantings in the entrance shrub clumps and the outer banks and shrub borders. The plan indicates the general way of grouping, with from three to six in a group. Among these evergreens various deciduous shrubs will come well. Blackthorn and dogwood (Cornus sanguineus) towards the outer edges, and inside, the two beautiful kinds of berberis, B. Darwinii and B. stenophylla, with the ever useful B. Aquifolium. Roses are not always successful near the sea; they dislike the salt-laden winds. But a notable exception is R. spinosissima and the whole range of Scotch briars that are derived from it; also sweet briar. Box-thorn or tea tree (Lycium chinense), that is so good for training over arbours, is a true seaside plant. It would trail down among the shrubs at the foot of the banks.

Carnations and pinks generally should be in the borders. Carnations grow vigorously and colour well, but in many cases have a curious habit of losing their scent by the sea.

THE FLOWER GARDEN

Early-Flowering Chrysanthemums

THE stools of the early varieties should be lifted now, and those required for propagation should be trimmed and placed in boxes or pots of sandy soil and stood in a cold frame. Keep them rather on the dry side until growth begins, when more ventilation and water should be given. Sturdy young basal shoots from these stools form good cuttings, which should be inserted in pots and grown on under cool conditions. If your stock has deteriorated in any way, or you wish to include some of the more modern varieties in your collection, here is a selection from which to make a choice :

AUSTRALIAN GOLD, *when disbudded, will make a fine large flower on a good stiff stem. Of a very rich golden buff, the flowers are incurved at the tips. Its season is August.*

BRONZE EARLY BUTTERCUP *has broad incurving petals of a chestnut bronze on the inside with gold reverse. Flowering in September.*

CRANFORD *is a fine variety, with golden yellow sprays, growing 4ft. high ; it will begin to bloom in mid-August and continue through September.*

CRANFORD CREAM, *shading to a primrose centre, is also excellent for sprays in mid-September.*

CRIMSON CIRCLE, *which blooms during August and September, is good for sprays or disbudding; it does not burn nor damp. Its reflex petals are of a deep rich blood red crimson.*

DICK BARNES, *a rich Burgundy, for sprays in September, is also good.*

GOLDFINDER *is, in the opinion of many, the best early yellow, whether for sprays or finer treatment.*

HARVESTER *is good, its yellow being shaded with bronze.*

ILLUMINATOR, *a lovely salmon shade with a bright gold centre ; it will disbud or make sprays.*

LICHFIELD PEACH (*peach pink*) *disbuds well and has good stiff stems.*

PHŒNIX, *a very bright scarlet bronze which has come to stay, will bloom from July till October. This variety is honoured by the market men, who certainly know the best.*

PINK DAME *will make sprays and has a very long season.*

PINK DELIGHT, *of good habit, will disbud, a lovely shell pink.*

RED ALMIRANTE, *a sport from Almirante, is good for sprays or single blooms.*

REINE DES BLANCS, *a white sort from, and an improvement on, that old favourite Roi des Blancs.*

SANCTITY *is certainly well to the forefront for white sprays in September.*

SALMON PROFUSION, *owing to its most fascinating colour and freedom of flowering, will be one of the most sought after of early chrysanthemums.*

SEPTEMBER GLORY, *when disbudded, with its large, well formed flowers of a brilliant orange bronze, will take a lot of beating, and is also very useful as a border plant when left to carry all the blooms it will.*

MRS. JACK PEARSON *is another very early bronze for sprays or disbudding.*

One word of advice to the older grower of chrysanthemums : Do not be afraid to discard old varieties or old stocks. The best cuttings are to be obtained from rested stock grown for the purpose.

Protecting Roses.

WHEN the weather seems likely to be very severe, the more delicate roses, like the teas, should certainly have some protection, otherwise they are sure to suffer badly. Of course, anything like coddling should be avoided, as this will cause the bushes to develop a tender constitution and also to start a premature growth in the spring—a habit which many of these roses are very prone to follow without any protection at all. Probably the best kind of protection is found in a few branches of fir, beech, birch, gorse and similar light boughs or twigs. Any of these are excellent to stick into the soil among the more tender of the dwarf roses. These will give ample protection against the winds and, after all, it is the frosty breezes that do more harm to roses than a still cold atmosphere. There is another great advantage of using such material instead of bracken or other litter. The latter is very untidy and also affords very much less protection just at the time when it is most wanted. Wet weather beats it down and it remains in a sodden state round the base or the most vital parts of the plants. Also, it is very troublesome to collect in the spring. The boughs are quite tidy and do not collect the wet. They answer a protective purpose all through the season and, when the spring comes, will still be playing a useful part in shielding the spring growth. For standard roses a few branches may be tied round the heads of the plants. All dwarf bushes should have the surrounding soil drawn up towards their base to a depth of at least 6ins. This is a very great protection, for it guards the most vulnerable part of the plant. Even should the weather be so severe that the tops of the plants are killed, the portion under the soil will remain unharmed, and this will produce many useful growths in the spring.

A PLANT FOR A SHADY SITUATION, RODGERSIA PINNATA.

A Fine Foliage & Flowering Plant.

FOR its foliage alone Rodgersia pinnata is a treasure invaluable, but when a plant is well established its soft, cheery flesh-tinted flowers, growing in spikes of as much as four and sometimes even five feet in height, are of wonderful beauty. The illustration conveys a good idea of the form of these flower spikes and shows also the beautiful veining of the foliage, but it cannot reveal the unique splendour of the rich copper-coloured foliage, which carries a gloss which reminds one of highly burnished metal.

Rodgersia pinnata should be provided with a recess where its growths may be shielded from rough winds and from the scorching heat of a summer midday's hottest sunshine. The screen may be of dark-leaved evergreen shrubs, so long as they are not rank growers, with ravenous roots, but I have seen very pleasing effects when a bay is formed by big boulders of rock at the foot of a rock bank facing west.

Deep digging, rubble drainage buried well below the roots, and a compost of peat and fibrous loam, admirably suits this plant, which should be given ample space for development at the outset (3ft. or 4ft. is not too much per plant), and thenceforward let it remain undisturbed. There is no objection to putting in a few roots of Anemone apennina or some erythroniums, snowdrops or Iris reticulata to prevent the wide area being bare when the foliage of the rodgersia cannot hide the soil. I have also seen liliums interplanted with fine effect.

The Alpine Flax.

LINUM ALPINUM, the alpine flax, is one of the alpine flora which have been in cultivation for many years, but which continue to retain their popularity despite the many novelties which have come to us from various quarters of the globe. It comes very near our own native Linum perenne, but is much dwarfer, and, with its prostrate, dwarf habit (it is only about 6ins. high) and its wonderfully large flowers, it looks very pleasing in the rock garden, although at home it is often to be found on grassland. The flowers are large for the slender, graceful, prostrate stems, and are of a delightful pale china blue, varying slightly in individual plants, and giving rise to a few varieties not usually in commerce. The flowers are produced in long succession, and this adds to the worth of this little plant. It loves a deep though poor and well drained soil in full sun, and is quite at home on the slopes and terraces of the rock garden. Plants can commonly be obtained in pots from nurseries dealing in hardy and alpine plants, and if in pots can be turned out at any time. Established plants may be divided, and a stock of

Digitized by Google

L. alpinum is soon raised from seeds, sown under glass in spring. Few rock gardens of any size are complete without a good clump or two of the attractive alpine flax.

Stonecrops for the Rock Garden.

THE genus sedum (stonecrops) includes many of the most attractive plants for the rock garden, and yet, with the exception of a few of the commoner species, it is quite inadequately represented in most gardens. This is a strange fact, since the majority of the species are perfectly hardy and the only conditions for which they ask are full exposure to sun, and light, well drained soil.

One of the chief points in their favour is that they are mostly evergreen, the foliage in many cases becoming beautifully tinted in the late summer and remaining so until fresh growth is made in the spring.

A few brief notes in regard to the best of them may be found useful. Perhaps gardeners will think that our native S. acre, which covers the stone walls of Gloucestershire and other counties with its bright golden flowers, is too common to bring into their gardens; but there are two varieties of it which should find a place, namely, S. acre aureum and S. acre majus (Maweanum), the former having pale yellow foliage in the early spring and the latter being a larger-growing form of the type.

The best grey-foliaged species is S. dasyphyllum, which is a real treasure, making compact mounds covered with tiny white flowers in the early summer. The soil should be specially well drained in this case, otherwise it is apt to disappear in the winter. S. Douglasii is rarely seen, although it is easy to grow and quite one of the best. It is about 6ins. high and its growth is somewhat woody. The foliage turns reddish in autumn and its bright yellow flower-heads are borne in June. A very distinct species is S. Ewersii, and, though hardly one of the best, it blooms at a useful time. The flowers are pink, produced in late summer, and the leaves are thick, flat and glaucous. The silver variegated form is much more desirable. An excellent paving plant is S. lydium. Its masses of green and red foliage are always a joy to look upon, but its flowers are rather inconspicuous, being very pale pink. Quite one of the best red-leaved species is S. oreganum with its succulent oval foliage and bright yellow flowers. We now come to S. pulchellum, which differs from its relations in having a liking for plenty of moisture during the growing season. The foliage is bright green during the summer, turning reddish in the autumn or when starved. The flower-heads are large and branching, with rosy mauve flowers. S. sexangulare is a very dwarf neat grower having golden flowers and is excellent as a paving plant. The sedum which no garden should be without is S. spathulifolium purpureum. It has greyish foliage in spring, turning bright red in autumn and winter and bearing handsome heads of golden yellow flowers in June. In conclusion, we come to S. spurium. There are a number of varieties in cultivation. One should select a good deep pink form, such as rubrum. It is a rampant grower and needs to be kept in bounds, but it is too good to be omitted. The foliage is green and rather large, colouring slightly in autumn.

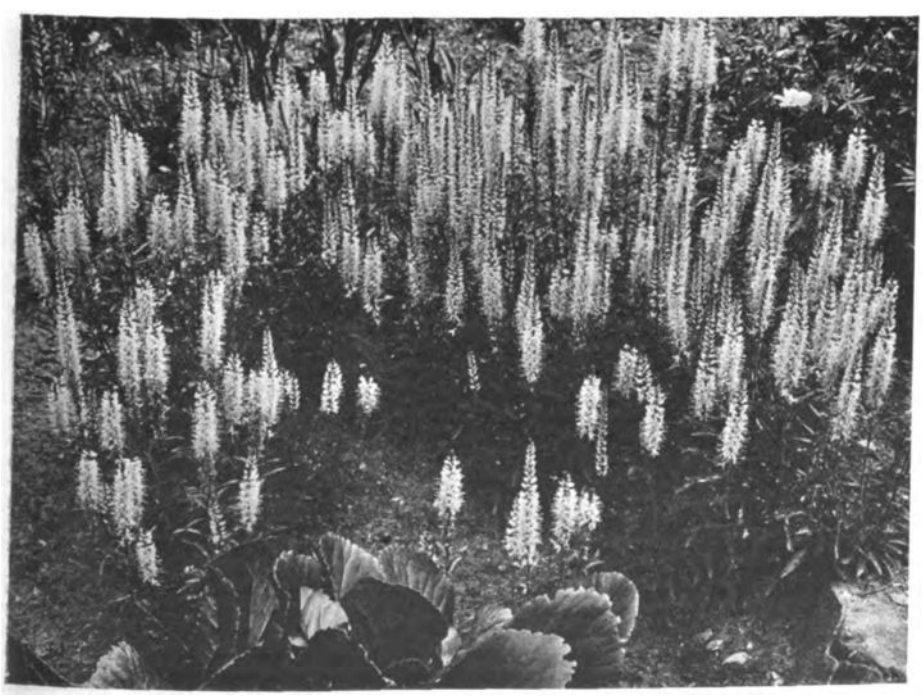
While this list could be greatly extended, the chief pearls of the genus will be found in it, and to increase it would be to make it difficult to select a small collection of choice and easily grown varieties.

SEDUM SPATHULIFOLIUM IS ONE OF THE BEST OF THE STONECROPS.

A Spike-Flowered Speedwell.

IT is in just such clumps or colonies as that shown in the illustration that Veronica spicata alba will reveal its full charm. Often one sees a solitary plant carrying one or two slender spikes, dainty and beautiful in themselves, but not quite bold enough really to make a striking display. In a mass, as our illustration shows, we get that striking display and still retain the extremely elegant and dainty appearance of the flowers. It is an easy matter to acquire stock for a good sized colony, for not only will strong roots split up for the making of several plants, but cuttings taken when the young growths are about 3ins. long will root readily enough in sharp, gritty soil. This plant, like the majority of veronicas will grow in any tolerably good soil and in almost any situation; it ranks in fact among the best of the shade enduring flowers and at the same time is a good dry-weather plant.

The way to secure the best results is to lift, divide and transplant every third year in a patch of soil that has had some manure worked into it two or three months before planting.



VERONICA SPICATA ALBA IS A FINE SPEEDWELL FOR THE BORDER.

The Goat's Beard.

THIS easily grown flower should be planted by the waterside; here it will show off its handsome foliage and flowers to perfection. It is a tall, shrub-like perennial, growing from 3ft. to 6ft. high; its leaves are long, pinnate and rounded at the base; the flowers are creamy white on long spikes, very erect. The Goat's Beard is most decorative and has a long period of flowering. We have seen it planted with the red bergamot (Monarda didyma), a most striking and pleasant association. Spiræa Aruncus is propagated by seed and root division; the latter should be done in early autumn, then the plants establish themselves before the winter.

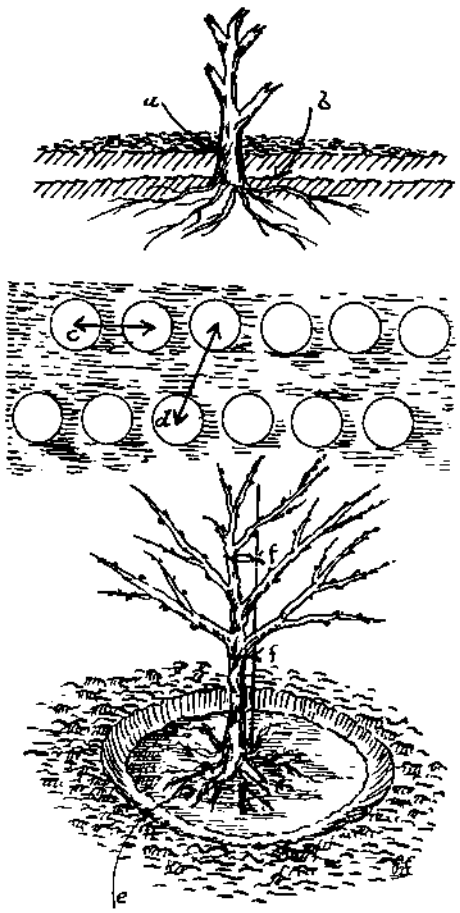
PLUMS and CHERRIES for PRESENT PLANTING

Fruit Tree Planting.

IT is not always possible to plant fruit trees in the autumn, but where it can be done, weather and other conditions being suitable, there is no doubt about it being a much better time than the spring. After autumn planting there are rains to settle the soil firmly round the roots, but after spring planting there is often a dry spell of weather and the soil remains very loose, in spite of treading, round the roots. Of course, it is absolutely necessary to plant in spring sometimes, and, when this is done, extra care should be taken to place very fine soil next to the roots, to firm well and surface mulch freely. In other matters do the detail work just the same as when autumn planting is carried out. All our trees should be grown, where possible, in an open quarter, but sheltered from the south and south-west winds—such shelters will be dealt with in a future issue of THE GARDEN. It is not enough that a hole should be made, the roots of the tree crammed into it and covered with soil. When a tree is once planted it is a difficult matter to do much to the soil about the roots afterwards. Everything possible should be done to prepare the soil before any trees are planted. A tree rarely succeeds straight away if its roots are "puddled-in," so it is important that the soil be fairly dry at the time, then it can be readily worked in about all the roots, large and small ones. Furthermore, the soil can be well firmed by treading; but treading, when the soil is in a pasty condition, would result in much harm. Often, the enquiry comes, "How deep ought trees to be planted?" A true guide is to note the depth that the tree was planted in the nursery, this can be ascertained by looking at the soil mark on the stem. Always have the soil covering the roots about 4ins. higher than the surrounding surface, to allow for them settling down to the normal level. At *a*, the depth is too great; at *b*, the correct depth to plant and cover the roots as shown. In block or plantation planting the trees should be arranged as shown at *c* and *d*, respectively; then they will receive the maximum amount of light and air. The hole should be made large enough to contain the roots in a spread-out form and their tips remain free from touching the sides, as shown at *e*. Before the soil is placed on the roots the supporting stake should be fixed and the main stem neatly fastened to it in two places, *f*, *f*. Even a bush tree should be so staked. Then finish the work by applying a mulch.



Best Plums.

THE prunus family requires a soil impregnated with lime and not too heavily charged with nitrogenous food. A deep, loamy soil is not so necessary in the case of plums as, say, apples and pears, as top-dressing with bone meal and short stable manure will greatly assist productiveness. These remarks allude to restricted systems, *i.e.*, bush, double cordons and fan-shaped trained trees. Summer pruning and washing and elimination of inside growth will greatly assist the well being of the tree and extend its life.

The following varieties will be found to suit most gardens, not only for free clean growth, but cropping qualities as well, the writer being acquainted with each and all.

Denniston's Superb Gage.—A first rate dessert plum, equal in flavour to and rather more vinous than Greengage. Ripe in the middle of August. Fruit, medium size, short, oval; skin pale yellowish green, marked with a few purple thin blotches and dots, and covered with bloom. Flesh yellow, firm, rich and sugary, adhering to the stone. Bush, double cordon or fan-shaped trees are best.

River's Early Prolific.—A variety of merit, answering equally for dessert or cooking purposes. Fruit small, roundish, coming into season during July; flesh yellowish, sweet and vinous, free stone. This valuable plum is now sought after by all commercial plum growers and was introduced by Mr. Rivers in 1866. All systems of training will suit the cultivation of Early Prolific.

Belle de Louvain.—A large culinary plum, coming to use about the end of August. Fruit very large and oval in shape, colour reddish purple, covered with a rich bloom; flesh yellow, firm, adhering closely to the stone; flavour good, does splendidly on a west aspect and very fruitful as a bush.

Czar.—A cooking plum, medium to large roundish, almost black, with a thin blue bloom. Very prolific and a reliable tree in all forms, a first-rate plum for the amateur, owing to its annual bearing proclivities.

Monarch.—This grand plum, raised by Messrs. Rivers, has proved one of their very best introductions, the fruits being of high quality and perfect in shape. Fruit large, oval, rich dark purple, fruit standing wet weather better than any other plum I know. All systems of cultivation will suit this late plum, coming in season in early October.

Belgian Purple.—Fruit medium sized, roundish, skin deep purple, covered with blue bloom, flesh greenish, juicy and sweet, very prolific and most useful for the amateur.

Pond's Seedling.—Fruit very large and oval shaped, skin dark red, with blue bloom, flesh yellowish, rayed with white and briskly flavoured, adhering to the stone. Ripe in the middle of September or thereabouts, very fertile and a splendid wall plum.

Purple Pershore.—A remarkably productive plum, most useful for bottling, preserving or daily use in season. Flesh yellow and of good quality. Makes a perfect half-standard or bush.

Victoria.—So well known, that comment is needless. The pity of it and more's the pity this excellent plum is so subject to silver leaf.

Gisborne's.—An excellent cooking plum, while the trees will bear themselves to death, it being so productive. Skin greenish yellow, changing to amber, with a few crimson spots and numerous russet dots interspersed. Flesh yellow, firm and briskly acid, free stone, coming to ripe in the middle of August.

Blue Rock.—A variety ripening in August, crop densely and worthy of extended cultivation. Fruit medium, round, dark purple, flesh yellow, juicy and sweet, and a variety of great excellence.

Reine Claude de Bavay Gage.—Fruit large, roundish and flattened at both ends. Skin yellowish green, sprinkled with dark red dots and covered with a delicate white bloom. Flesh yellow, tender, melting and very juicy, with a rich sugary flavour, free stone. Ripe in the end of September to middle of October. Growth moderate, hardy and fertile.

Best Cherries.

ONE of the most luscious fruits known, yet so seldom met with in the amateur's garden. I presume there are reasons for this scarcity of planting, probably owing to attacks of cherry aphis, gumosis and sterility.

Cherries require a soil heavily charged with lime, and root action, should be undisturbed.

Selection of varieties is of great value and it is wise to plant two or more varieties to enable cross fertilisation, this being a decided factor towards a successful crop.

A west or south-west aspect is favourable to their well being, while summer pruning and cleaning of the trees during the summer all tend towards a profitable issue.

The following sorts will be found useful for the small garden:

Waterloo.—A large, dark purple fruit, raised by Mr. T. A. Knight in 1815 and named a few weeks after the occurrence of the battle of Waterloo. Skin thin, dark purple, mottled with brownish red and becoming almost black when fully ripe. Flesh red and darker in colour near the stone, tender, juicy, with a rich, delicious flavour and excellent in every way. Free grower and a good bearer, coming into season from mid to end of June.

Knight's Early Black.—Fruit large, obtuse heart-shaped, skin nearly black when fully ripe, flesh dark purple, tender, juicy and sweet, richly and highly flavoured. The tree is healthy in growth and most productive in company with other varieties.

Napoleon Bigarreau.—A large heart-shaped fruit with a brilliant scarlet cheek on a pale yellow ground, very handsome and taking. Flesh firm, juicy and sweet, in season in August, tree vigorous, hardy and prolific. A splendid wall fruit in company with others to enable fertilisation.

Black Heart.—A cherry of great antiquity, and still one of the best. Fruit large, heart-shaped, flesh dark purple, firm, sweet and delicious, growth vigorous and productive.

Governor Wood Bigarreau.—Large heart-shaped fruit, in season in July. Fruit pale yellow with a light red flush, flesh tender, sweet and juicy. An excellent cherry for the garden or orchard house.

Kentish Bigarreau.—A very old variety of great value, of medium size and extremely productive. Fruit pale yellow, with bright red cheek, flesh white, juicy and sweet. A good grower and crops immense on all systems of training. For one variety this can be thoroughly recommended.

THE BUSY MAN'S PAGE

Black Currants.

THESE succeed best in well dug, cool, moist soil. A position in partial shade is often very satisfactory. At the time of planting—which can be carried out during open weather from now until early spring—a moderate dressing of well decayed farmyard manure should be thoroughly worked into the soil. The bushes should be planted 5ft. apart each way. By planting a selection of suitable varieties, the fruiting season can be prolonged considerably. During the summer a mulching of rotted manure is most beneficial.

BALDWIN. — *Heavy and regular cropper. Fruit is sweet, firm and hangs late.*

BLACK CHAMPION.—*Early. Large, somewhat acid berries, bunches long.*

BOSKOOP GIANT.—*An early variety. The largest black currant with a long bunch. Growth is free and spreading and the fruit is tender and juicy. A good variety for all positions.*

DANIEL'S SEPTEMBER.—*A fine new disease-resistant variety which ripens three or four weeks later than any other black currant. The bunches are long and the fruit jet black. It is a strong grower and a heavy cropper.*

SEABROOK'S BLACK.—*One of the best black currants. It is resistant to big bud, very prolific, vigorous and crops remarkably well. A mid-season variety.*

How Frost Benefits the Ground.

THE thorough breaking up of the soil is of the greatest importance to every gardener. A great deal of this disintegration is secured by digging and other processes, but it should not be forgotten that there are powerful natural agents which play a very helpful part in the business. Water, especially in conjunction with frost, plays a very big part in bringing the soil to a state in which plants will flourish. When the moisture in the soil freezes it expands and tears the clods of earth asunder. Thus, after a severe frost, the ground is always seen to be covered with fine mould. Land which is unoccupied during the winter, especially heavy soil, should always be ridged up or hoed into drills as for potato growing. This allows free play for frost and lets the cold penetrate the ground in all directions. If possible, let the ridges run north and south, so that, in addition to the frost, sun and air may get at all parts. These natural agents working together on the soil bring it into an excellent condition.

Destroying a Tree Stump.

WHEN a tree has been sawn down it is often a difficult matter to remove the stump and roots. By far the quickest way of getting rid of the stump is to burn it up in the following manner: With an augur bore several holes as deeply as possible in the stump. A slower way of getting out the holes is to burn them out with a red hot poker. All the holes are then filled with paraffin. As the oil soaks into the wood the holes are refilled, and this is done on several occasions. After three or four days the stump will, to a large extent, be heavily impregnated with oil. Now collect a quantity of dry stuff and pile this lightly right over the stump. Set the mass alight and soon the oil-soaked stump is blazing away merrily. The burning process will go on for some time, and in the end the whole of the stump and most of the roots will be reduced to ashes. It will now be quite a simple matter to clear the ground, and the ashes which have come with the burning of the stump should be scattered over the ground and dug in on account of their fertilising properties.

The Many-Petalled Kingcup.

CALTHA POLYPETALA, the many-petalled kingcup, has been long enough in our gardens for its value to be properly appraised, and it must be said that it is a plant of great merit. It is effective in every way. Its tall habit, its large handsome leaves, and its noble cups of golden yellow borne throughout the summer, all give it an undeniable claim as being among the plants well to the front in the garden where there is some moisture to sustain its growth and satisfy its tastes. It grows to about 3ft. high, a sufficient height to put it well above the other kingcups. Then, the leaves are no less than a foot across; while the stout stems bear their handsome golden yellow single flowers all summer through.

Caltha polypetala, like its kindred kingcups, is a moisture-lover, and, given a good place by the side of a stream or pond, where its roots can reach the water it so much desires, it will give splendid results and produce a capital effect. Propagation is performed by division.

THE GOLDEN BLOSSOM OF THE MANY-PETALLED KINGCUP.

A Chrysanthemum Hint.

WHERE accommodation for all the late-flowering chrysanthemums cannot be found in the glasshouse the following plan is to be highly recommended. Select the sunniest wall in the garden and here arrange the plants with care, letting the tall ones be placed behind and the short ones in front. Not only may chrysanthemums in pots be so placed, but late varieties in the garden that are threatened with the bad weather may also be lifted and transplanted along the base of the wall. The developing flowers may be protected by putting a few boards against the wall. Another plan is to drive nails in the wall and to these attach pieces of matting or old sacks, the other side of the material being fixed to uprights which have been driven into the front of the border. The protective covering will be most needed at night, and on mild, sunny days it may be removed for a few hours round about noon. When the weather is cold and wet the protection may be left on throughout the day. Chrysanthemums treated in this way may be nursed through many weeks of bad weather, and it is often possible to keep up the display until well into December.

Preservatives for Wood S

IN the case of all wood support have to remain in the soil for it is a real economy to employ som tive so as to arrest the process which sooner or later would rot completely. For this purpose handiest thing to use is gas ta gallon or so of the tar out in th placing the can over a small fire is conveniently built up round which the can is rested. When thoroughly hot paint the wood about 6ins. above the ground level tar-covered parts of the sticks in a sand and then put them on one sid

LOOK AFTER YOUR SOIL

At this time of year the correct treatment of the soil itself is most important. If your plants are to succeed, then the soil must be suitably prepared for their reception.

nd Spades.

he most useful tools in the garden rks and spades, and when buying ys to make sure that one is getting rm of these implements. The most type of digging fork is one with ines and with points that are not This tool will be strong, but is to damage roots than one with nes and very sharp points. It is natter of choice whether the handle ox or the crutch pattern. In using general practice is to have the on the top of the handle and the lown near the prongs. Some people the positions and do just as good ally, it is rather a good plan to e a fork in both ways, even if one rally ambidexterous, for an occa- nge over will very much reduce of digging. Wherever a fork can stead of a spade, for turning, it is th while doing so. The work will asier and the best gardener should nomise labour where he can do so rificing efficiency. Always employ digging among plants in borders uch operations as lifting roots, manure, etc. A hand-fork is most dealing with small plants, and it ss likely to cause root injury than A spade, to be really handy, should heavy. A moderately light spade long as a heavy one if it is properly Once a spade is really bright by housing it in a dry place. It lent plan, after cleaning away the the blade with an oiled rag. Of mmon sense dictates that a spade be used where roots are just surface.

Soils.

om which water does not readily way are cold and more or less for that reason, good drainage ed to be one of the first essentials mpts to increase the fertility of ; moreover, stagnant soil-water gainst healthy bacterial action, ential to intensive gardening. The method of draining a garden is rain through it, along the line of vo or even three, when the garden In wet districts there might be a 12ft.; in porous loam, if drains ry, they may be 18ft. apart. It vantageous to lead a drain down d to run a few branch drains into ise is one which demands individual and yet no expert knowledge is re the area to be dealt with is not el garden the drain itself must e. The trench at the beginning out 2ft. in depth, sloping to 3ft. he other end. The normal trench ft. deep, the less depth in heavy am. ins are a foot long and about 3ins. ; knowing the length, the gardener ufficient from dealers, or he may gain with some farmer ordering a or even a nurseryman, a house- a jobbing gardener. If drain tiles secured, dig the usual trench and ly with clinkers, stones, tins, or bunches of twigs tied firmly a point to note in all cases is that s free enough to allow the water ay; it may lead into a sewer, a o another drain. In difficult cases, hole, fill in with stones, and lead the drain into this. In very small gardens of a damp nature, a deep hole may be dug just now; into it is cast the winter's accumulation of stones, tins and all sorts of rubbish. Covered with turf in spring, this may be hidden with soil, but it continues to act as a drainage hole and materially dries up the surrounding ground. In lawns, round fruit trees and elsewhere the process known as "holing," in which fairly deep holes are made with a crowbar or fork, is well worthy of adoption, as it has the power of drying and sweetening the ground where it is carried out.

Stacking Turf.

WHEN opening up a new plot of ground there is often a considerable amount of rough turf to be removed. This may be of no use for lawn making, but, if it is of a fibrous nature, it should be carefully cut to the depth of 3ins. or 4ins. and stacked. The reason for this is that such turf forms the best possible potting soil on account of the rich store of plant food which it contains. Turf is stacked for greater convenience, as it is not always an easy matter to cut it just as it is needed, and then it improves enormously with keeping. If closely stacked one can smother out most of the weeds and also discourage many insect and other pests. Still further, stacked turf may be rendered even more valuable by the incorporation of manure. The best time for the cutting and stacking of turf is in the latter part of the year. It does not matter much what is the shape of the stack so long as the upper part will throw off most of the rain. To enrich it put a layer of well decayed manure between each layer of turves. This will do away with the necessity of adding manure to the potting mixture. Leaf-soil which is about a year old might also be worked in with advantage. If insects and grubs are seen to be wriggling about, dust the turves freely with soot or lime and so destroy them.

Manures for the Garden.

FARMYARD MANURE.

THIS term may include that of horse, cow and pig manure. Poultry manure is sometimes mixed with the other manures of the farmyard, but generally it is placed in a heap by itself. For garden purposes cow and horse dung are no doubt the best. Littery stable manure is the best sort of heating material for a hot-bed, but well rotted cow dung is the most suitable for digging into flower and vegetable plots and for general manuring purposes. Pig dung is good for roses and for general cropping; but it is unsuitable for a turnip crop, especially where there is a tendency to anbury, or finger-and-toe, by reason of its acidity or sourish condition.

POULTRY MANURE.

This manure, when dried and seasoned, is about as good as guano. It is too rich to use generally on a liberal scale, but may be applied in good measure to those gross-feeding crops of the cabbage tribe, leeks, etc. It should always be well rotted so as to make sure of any seeds it may contain being destroyed. If mixed with decayed compost, such as turves, leaves and other herbage, poultry manure makes a good fertiliser for any kind of crop. It may also in such form be incorporated in potting composts.

Poultry manure may be utilised in the production of littery material for a hot-bed. Dissolve the poultry manure in tubs of water, adding as much liquid manure as can be collected from other sources. Get ready a heap of straw, well mixed with green herbage, leaves, etc. Pour the liquid manure thus prepared over the heap of straw, which, by the way, should be piled in a kind of pit well bottomed with clay. When the heap is fairly well saturated, throw some old bags or other material over the top to keep the hot vapour in and the rain out. When the heap has fermented sufficiently, turn it over on a dry position and sprinkle a little more liquid manure over the successive layers. Turn the heap a few more times until it is in a condition to make a hot-bed.

How to Renew Soil with the Least Damage to Plants.

THIS is a subject that requires care and discretion, but at the same time it presents no difficulties to the plant lover.

Once a year the whole of the rock garden should be gone over carefully and the roots of the plants top-dressed with fresh soil to provide nourishment for the following season of growth, and such work can be performed during the latter part of the year, excepting, of course, frosty weather, and also in spring. All dead growth must be removed and a little of the old soil picked out with a small hand fork or zinc label, without any injury to the roots. This refers to the stronger-growing subjects. The weaker brethren with less vigorous roots must not be treated so severely, while others with plenty of live roots on the surface will not require any of the soil being removed, but just top-dressed with new material. Great care must be taken to obviate any harm coming to the centre of the plants, and the depth of the compost will depend on the subject top-dressed. For instance, rock roses would benefit by a generous application, while for androsaces and such like a mere sprinkling of the leaf-mould and sand mixture would suffice. Whenever fresh soil is given it must be made fairly firm, otherwise it will not be of any advantage to the plants. In every rock garden a few alpines at least will be found in anything but a thriving condition, and in such cases it is advisable to lift the plants and replace the old soil with new before replanting, or remove them to another station. The latter method often proves the most satisfactory. With fissures and crevices the work of top-dressing needs a little more patience, and in some instances no additional soil will be necessary. Take the ramondias and Saxifraga longifolia, if the fissures were well packed with proper soil at the time of planting, nothing more need be done for two or three seasons. If the soil has become sour, and therefore not conducive to free root action, as much as possible should be picked out, and replaced with other soil. When doing this a small rammer will be useful, because in such positions the soil must be made firm and with a little practice it will be found quite easy to pack a fissure or crevice so that the plants will be quite happy. In renewing soil without any undue disturbance or injury to the plants, the left hand must be made to do its share of the work, by taking care of the top of the plant. It can hold the growth on one side, or prevent the small evergreen shoots from being damaged. At the same time the right hand will be carefully picking out the old impoverished soil and placing the new mixture in position. In this way the work will be accomplished with a minimum of damage, and in due course the result of one's labour will be apparent.

SOME PLANTS FOR A DAMP SPOT

FEW small gardens can boast of anything in the way of a stream or pond, but in many there is a damp place—even if only the result of the recurrent overflow of a tank—in which plants that only drag out a miserable existence in an ordinarily dry border, will take a new lease of life. All the cimicifugas—of which racemosus and cordifolia are the best known—for instance, do most satisfactorily where they can get a little moisture at the root and, if possible, a little shelter from the midday sun, rarely reaching their full height of 5ft. or so, or opening their long creamy white spikes properly under other conditions. Physostegia virginianum is another plant which flags badly in hot weather in dry soil; the lilac-pink blossoms of this, borne in branching spikes, are very pretty and have the advantage of being admirable for cutting. There is a white variety but this seems less free-flowering and even more resentful of drought than the type. The herbaceous spiræas—the tall Aruncus and the lower-growing filipendula and palmata—all thrive best in a damp corner, as do their kindred, the astilbes, of which Davidii is imposing for the back row, although its colour, crimson purple, does not appeal to everybody. The hybrids, said to be the result of crosses between A. Davidii and S. japonica and S. astilboides (of which there are fourteen or fifteen named varieties in white and various shades of pink), are effective, but are not always absolutely hardy in cold districts and are better suited, perhaps, for pot work. Thalictrum glaucum and Senecio tanguticus are two other plants that revel in a little moisture. Both are six-footers in quarters they like and the golden yellow spires of the latter are showy (and good for cutting) in late August and September, but it is a terrible encroacher and needs careful watching. The great orange coloured umbels of another member of the groundsel family, S. Clivorum, are handsome enough to make amends for its ugly coarse foliage, but it has a fatal

A PATCH OF POLYGONUM AFFINE WITH REDDISH PINK FLOWER SPIKES.

attraction for slugs and snails, unfortunately. There are, it is almost unnecessary to say, several species of iris suited to a damp spot, but none is more beautiful in a large background group than the giant I. ochroleuca, the white and gold flowers of which not only last a long time individually, but will continue to succeed each other to the number of four or five on each stem, whether growing or cut and in water.

Among the plants of medium height that will thrive in the damp corner are the trolliuses, europæus (lemon yellow), asiaticus (orange), and their hybrids, of which Empire Day is perhaps the richest in colour; the day lilies, especially the tawny Hemerocallis fulva and the pale yellow, sweet-scented H. flava, rarely absent from old gardens; Cardamine pratense fl. pl., the double Lady's Smock; and Polygonatum macrophyllum (one of the Solomon's Seals). Lobelia cardinalis would supply a welcome touch of brilliant colour, but in all but the very warmest parts of the country it must be lifted before the winter, which is tiresome. The gorgeous scarlet Lilium chalcedonicum is quite hardy, however. Damp is not generally considered essential to the well being of this fine lily, but it certainly likes it and if in a dry border it is apt to be disfigured by its leaves yellowing before the flower opens. It has two drawbacks—it does not increase rapidly, hence its comparatively high price, and it often gets eaten off by slugs directly it appears above ground. Another suitable plant of good colour is Monarda didyma, but it must not be overlooked that its crimson will clash with scarlet.

For the front of the damp patch there are the reddish pink Polygonum affine, Mimulus luteus and M. cardinalis (doubtfully hardy this, however); the two blue flowered plants Anchusa myosotidiflora and Omphalodes cappadocica; Myosotis palustris (for the wettest place), and, if there is peat in the soil, the beautiful wood lilies (trilliums), with their delicate white or pink flowers. If a trailer is wanted, there is the ever useful Lysimachia Nummularia, the golden-starred trails of which look their prettiest veiling an old tree stump or a heap of rockery stones.

R. E. HEAD.

WHAT OUR READERS SAY

ROSE K. OF K.

SIR,—I am surprised that K. of K. is not more recommended for rose gardens. With me it is very strong growing, the bloom lasts well on the tree and unusually long indoors. By artificial light the colour is wonderful, even a half dead one lights up into a gorgeous red such as I have seen on no other. A great part of its night beauty is due to the delicate bloom on its petals.—M. RUTHERFORD, *Cambridge*.

A USEFUL PLANT FOR THE AMATEUR.

SIR,—The accompanying illustration depicts a flowering spike of the garland flower (Hedychium Gardnerianum), which is one of the sweetest, cool house flowering plants in cultivation. Its generic name is derived from the Latin words, *hedys*, sweet and *chion*, snow; alluding to the sweet scented, snow white flowers of some of the species.

This species was introduced into this country over 100 years ago and specimens of it may be found in all the best gardens in the land. It is, however, essentially a plant for the amateur who has only a slightly heated greenhouse. In fact in the southern parts of England it is reputed to be hardy in sheltered spots.

H. Gardnerianum grows to the height of about 4ft. and the top of each shoot is surmounted with an enormous spike of large, fragrant flowers of a clear lemon yellow colour, against which the reddish stamens show up in great contrast. The requirements of this plant are of the simplest. It should be planted in a large pot or tub, or in a prepared border in the greenhouse or conservatory. As it is a prolific growing plant it must be provided with a rich compost, consisting of two parts of loam, one of leaf-mould and half a part of well decayed manure. Potting should take place in March or April and a liberal supply of water provided as the growth becomes vigorous. After flowering, water must gradually be withheld, so that the soil is kept in a dry state during the winter.—G. F. GARDINER.

THE GARLAND FLOWER.

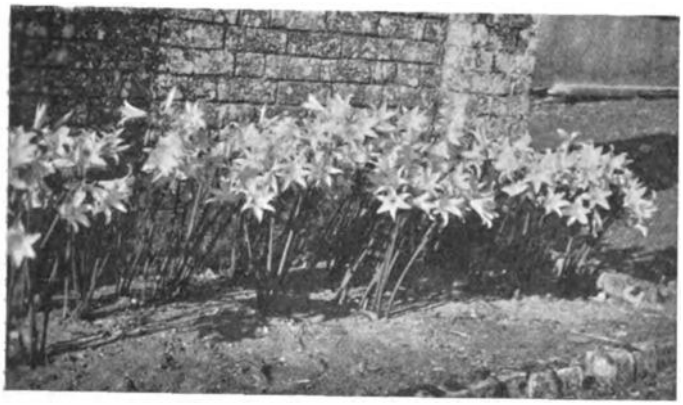
LIME-LOVING LILIES.

SIR,—On page 542, in a friendly endeavour to help "Ignoramus" to an understanding of the way of lilies, "Ignotus" wrote that, with the exception of a few species which he enumerated, the great majority of lilies are definite haters of chalk and lime.

As this rather sweeping generalisation may deter some of the many who garden on limy soil from attempting the cultivation of lilies, I venture to suggest to "Ignotus" that his dictum needs some qualification, and the inclusion in his list among lime-tolerant lilies of all the European species—LL. chalcedonicum, pyrenaicum, pomponium, croceum, bulbiferum, carniolicum, Martagon and Szovitzianum, as well as testaceum and umbellatum.

Of Japanese lilies which tolerate lime, L. Hansonii is easy to manage, and among the many American lime-loving or lime-tolerant

Digitized by Google



A ROW OF BELLADONNA LILIES.

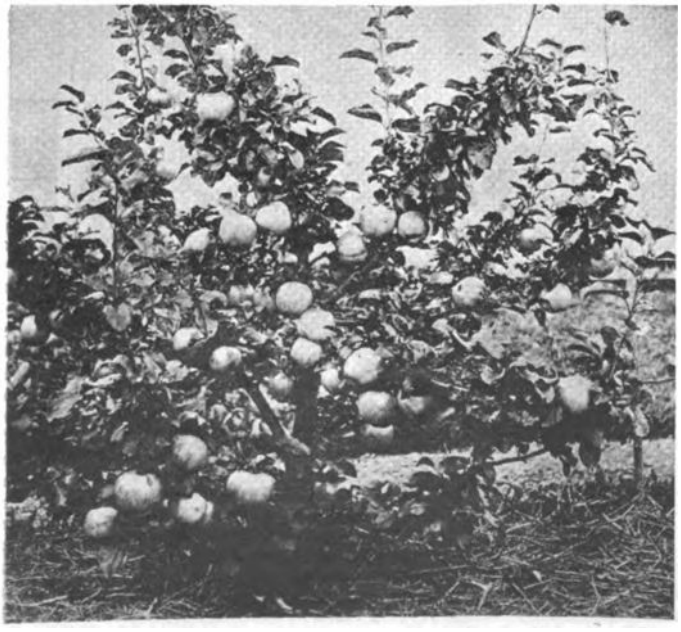
species, L. pardalinum is surely within the power of the novice.—A. GROVE.

THE PROBLEM OF THE HEDGE.

SIR,—In an article on the above in the issue of October 23rd there are mentioned various substitutes for the conventional dwarf box edging. Last autumn, wanting to plant such a miniature hedge, I was advised by a local gardener to try Santolina instead. The plants were put in about 9ins. apart, and in the spring, when new growth started, they were clipped to about 4ins. from the ground. Since then they have been allowed to grow into a very attractive hedge 10ins. high by 12ins. thick and about 50ft. long, crowning a low terrace wall. Of course, three or four clippings during the season and not permitting flower buds to form, are necessary to produce good results.—L. PETTITT, *Bournemouth.*

APPLE REV. W. WILKS.

SIR,—Although it is upwards of twenty years since this variety was introduced, it cannot be said to have found its way into the gardens of the average small grower to any great extent. It is hard to say why this is so; for it is a truly fine kitchen apple of more than usual fertility. The apples are large, noticeably so, and good cookers; while the habit of the tree is dwarf and strong growing. The season of this variety is October to November, and anyone requiring a reliable culinary apple will not be disappointed with a trial planting. —C. T., *Ampthill.*



A GOOD COOKING APPLE, REV. W. WILKS.

AMARYLLIS BELLADONNA.

SIR,—I am enclosing a photograph to show the extraordinary free-flowering of the belladonna lilies this autumn, as mentioned by Mr. Woodall on page 604. The original bulbs in the photograph, ten in number, were brought from Colombia, South America, in 1920. They have flowered well each year, usually throwing about thirty spikes; but this year they have exceeded all expectations and thrown the remarkable number of 105 spikes.—E. HAYWARD, *Wimborne.*

STORING APPLES ON STRAW.

SIR,—In your valuable paper an illustration appears on page 621, October 30th, showing the storing of apples on straw on a shelf. Now, Sir, if there is a fruit which can be tainted by foreign matter it is the apple. Last week a friend gave me a James Grieve apple, but I am sorry to say it was uneatable owing to it having been very much tainted with straw—dry straw having been used to protect bulbs from frost in the fruit room. Apples tainted with straw always remind me of "fresh Irish eggs."

Apples to be stored should not be placed in a room where any foreign matter is kept, not even among straw, if the natural flavour of the fruit is to be preserved. Fruit room shelves are best made of stone or slate, or a coating of clay about an inch thick placed on the wooden shelves. Stone slabs or clay keep the temperature cool and sweet. The best kept apples I ever tasted for flavour were those which had been stored in an unused ice-house under the ground level—GEO. STUART.

SKIMMIA JAPONICA.

SIR,—In recommending Skimmia as suitable for a small garden (page 623), "E. C." would have done well to point out that, whereas Skimmia Fortunei is hermaphrodite, ensuring a crop of dull red berries on every bush, S. japonica is dicecious and none of its brilliant scarlet fruit can be borne on a solitary bush. It is essential that there should be a male staminate plant placed near the female pistillate plant, else there will be no display.—HERBERT MAXWELL, *Monreith.*

A SLUG COLLECTION.

SIR,—I thought perhaps it might be of some interest to your readers who have been troubled with slugs in their gardens to know the number I have destroyed in my garden between April 11th and September 17th of this year. I kept a record each day, and the aggregate amounted to 30,370. In addition, my gardener killed a large number, but no record was kept of the quantity he accounted for. Among the above number there were about six different kinds, but the small black ones predominated.—W. E. O. WILLIAMS, *Chepstow.*

WHAT CAN BE ACCOMPLISHED IN A YEAR.

SIR,—The enclosed photograph of my garden was taken just one year from the time I took possession of it, when it looked to many a hopeless mass of heavy, clayey soil, just as the builders had left it; however, being a keen amateur gardener myself, I felt confident that with the aid of your valuable paper and a little hard work I could get it in order. Having ultimately decided on my scheme, I proceeded to excavate and level certain portions, as the land had a considerable incline towards the house, but I overcame this difficulty by forming two steps, utilising the mounds, one each side, for a rock garden, under which I dug sump holes for drainage. The concrete vases I built up on two large flower pots bolted together and cemented over and stood on a rough brick base, the stones of the rockwork abutting them on either side; immediately at the top of the steps is a gravel walk which winds round on the right-hand side and through the archway, where it divides a small fruit garden on the one side and a vegetable garden on the other. Good wide herbaceous borders are formed on both sides of the flower garden, reserving the centre part for a small lawn, with narrow rose beds cut out in the turf; a grass verge also winds round on the one side with the path. The rose arch is quite a substantial one which I erected and planted with climbers the first winter. I may say that I had absolutely no help with the work, everything being done by myself in my spare time. I was fortunate, however, in securing a fair stock of perennials from some of my gardening friends when they were dividing them, and the roses I purchased elsewhere; thus I managed during the first year to make quite a presentable little garden and I am quite satisfied with the results of my labour.—GEO. W. HALL, *Eltham.*

A PLEASANT LITTLE GARDEN A YEAR AFTER FORMATION.

Digitized by Google

MICHAELMAS DAISIES.

SIR,—The opening paragraph on Michaelmas Daisies in the issue for October 30th, page 615, is calculated to deter the man with little time and a small garden from planting these delightful autumn flowers. Though some of these perennial asters are rampant growers, there are many of the best modern varieties that may be planted without the slightest fear of their becoming a nuisance.

Here are a few I have grown and can recommend: Mons, Brightest and Best, Royal Blue, Blue Gem, Anita Ballard, Ethel Ballard, Rachel Ballard, Purple Emperor, Snowball, Dick Ballard, Little Pink Lady and Little Boy Blue. These give a good selection of colour, and all form compact roots; indeed, some are rather slow to increase. All may be left for two years, and other plants in the vicinity will not be smothered by runners from the original plant.—B. A. BARRETT, *Thames Ditton.*

A GOOD PHILADELPHUS.

SIR,—May I put in a plea for Philadelphus Purple Eyes for a small garden. It is so neat, floriferous and delicately fragrant that I think it should be better known. Here it does well in rather heavy loam in a somewhat cold position.—C. M. A. P., *Newbury, Berks.*

HOW TO MAKE A GARDEN ARCH

THE garden arch shown in Fig. 1 is made of substantial material and the method of construction is not beyond the capabilities of the average amateur woodworker or handyman. Although the arch is dimensioned for a path of 3ft. 6ins., the width can be altered

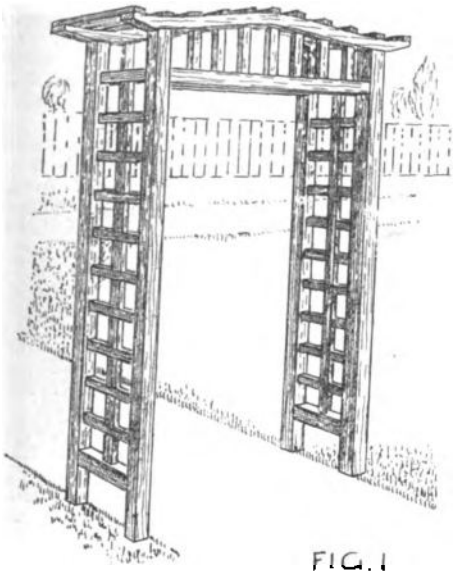


FIG. 1

without interfering with the construction. The uprights and principal cross-bars are of 2in. by 2in. material, of which 50ft. run will be required in lengths sufficient to cut four 8ft. 6in. posts. The shaped top can be cut from one 4ft. 9in. by 6½in. by 2in. piece, or two 4ft. 9in. by 4in. by 2in. pieces. The remainder of the stuff is 2in. by 1½in., 75ft. run being sufficient to allow for a little waste. The wood, preferably oak—though deal, on account of cost and ease of working, may be substituted — should be obtained machine-planed to the sizes given; but if it is a little smaller, due allowance must be made in marking out.

First cut off the four posts A to 8ft. 6ins.; mark off 1½ins. at the top and 1ft. 9ins. from the bottom. These marks should be made on all four pieces at the same time as they lie side by side. From the top mark set off 8ins. to give the position of the top of the two sets of top bars B and C, and mark off 2ins. below the mark and 2ins. above the bottom mark to give the length of the mortises marked *b*, *c* and *d* in Fig. 3. Next set out the eight mortises in between; these are 2ins. long and spaced out equally as indicated at *e*. The two bars at B are cut to 3ft. 8ins. long, with tenons 1in. long at each end, as at Fig. 3. The side bars at C and D are cut from the 2in. by 2in. stuff to 16ins., with tenons 1in. long and the inner bars E cut to the same length from the 2in. by 1½in. material. The width of the tenons for all the joints is ⅓in., so gauge lines this distance apart can be made on the ends of all the pieces B, C, D and E. The upright pieces each side, shown at F, are cut from the 2in. by 1½in. stuff to a length of 5ft. 9ins., the tenons on the ends are 1in. long and are fitted in mortises cut in the bars C and D. The eight grooves as shown in Fig. 3 are 2ins. wide and ⅛in. deep, similar grooves being cut in the cross-bars E. The easiest method of marking them out is to fit all the short bars in between the upright posts, place the long strip F in position across them, and mark each joint separately.

In order to make the construction quite clear, enlarged details of the joints are given in Fig. 4. The correct method of cutting the tenons is shown at T, and it will be seen

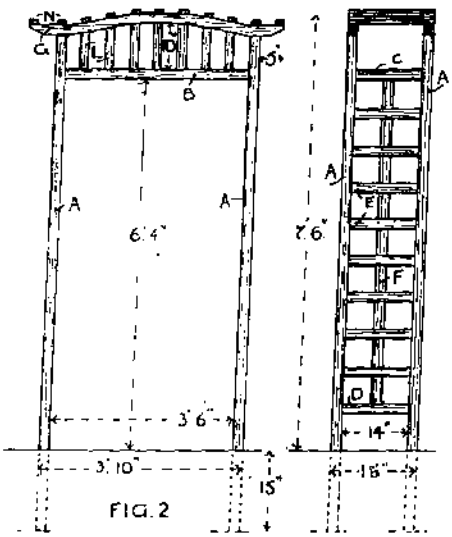

FIG. 2

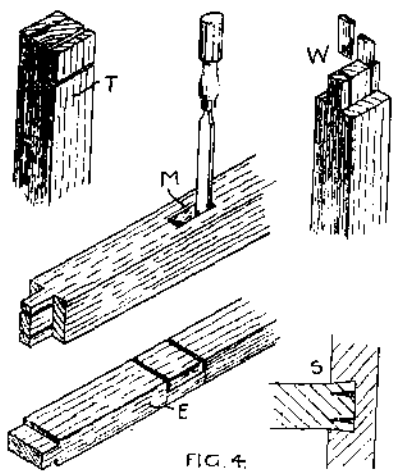

FIG. 4

that the saw cuts are made on the waste side of the lines. The method of cutting the mortises is shown at M; the bevelled side of the chisel should be on the outside of the cut until the finishing cuts, when it should be on the inside. Beginning from the centre, work from each side of it in turn, gradually removing a wedge-shaped hollow. The finishing cuts will not be difficult after the waste has been removed. The method of cutting out the grooves for the pieces marked E and F is shown at E, care being taken not to saw beyond the marked lines and to cut half the thickness of the wood away.

The shaped top, G, can be cut out with a bow-saw and finished with a spokeshave or drawknife, the method of marking out the wood being shown at H in Fig. 5. The wood should be 4ft. 9ins. long, 6½ins. wide and 2ins. thick, the rise of the curve being 2ins. If a bowsaw is not available, an alternative method is shown at J; in this case each shape is cut from wood 4ins. wide. The method of sawing with a handsaw is shown at K, the final shaping being done with a spokeshave. The top pieces should be placed in position on the top of the posts and then the short uprights of 2in. by 1½in. wood marked off to length, allowing for 1in. tenons at each end.

The best method of securing the joints is shown at S, two narrow wedges being fitted in at the edges of the tenons. The tenons are cut down as shown at W, so that wedges, cut to the length of the tenon, can be inserted. The inside of the mortises are widened out at the base to allow for the spread of the tenon. There is no need to wedge the tenons on the strips E, F and L, but all the other joints should be done. The framing should be glued together, first the side frames complete, then the cross-bars B, and finally the shaped top G and the short uprights L. The strips N across the top are all 18ins. long and cut from the 2in. by 1½in. wood; they can be nailed in position. The bottom 15ins. of the upright posts, A, should be coated with melted pitch, and the rest of the wood either varnished or coated with a wood preservative.

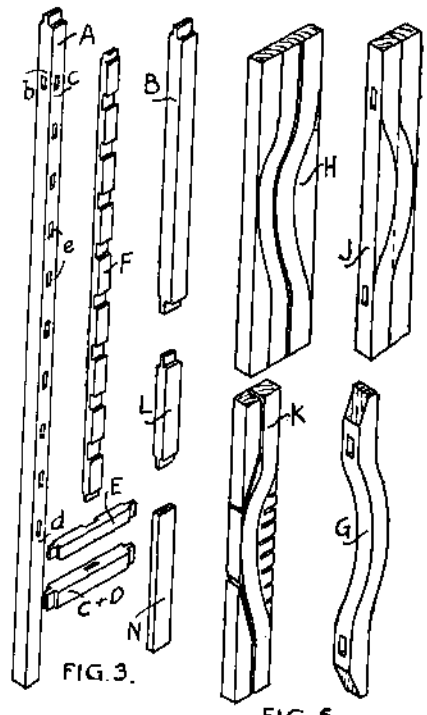

FIG. 3.

FIG. 5.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Each must be sent in on a separate sheet and must not be more than 300 words in length.

THE HALF GUINEA HINT.

To Destroy Nettles, Bindweed and Groundash.

A good way to destroy the above is to spread weekly lawn mowings over the ground infested, covering all growth as it appears in this way. The writer successfully destroyed beds of nettles, bindweed and groundash practically in one season. The bindweed was a mass nearly smothering a plantation of gooseberries. After one season all the weed left was easily forked out. This ground was cleared fifteen years ago and no bindweed has appeared since. This method also manures the ground to a great extent.—G. J. W.

A Pot Propagator for Cuttings.

A simple but efficient propagator for cuttings which are difficult to root, or seeds which are difficult to germinate, may be made as follows. Place a small pot, inverted and filled with moist fibre, inside a large one, fill in with soil until the smaller pot is covered and then plant the cuttings in two rings or one ring, according to size. Place the whole arrangement inside a still larger pot or box and pack moist fibre loosely round it. A glass can be laid on top. The increased wall area obtained by this propagator and the moisture on the outside of the porous pots, serve to draw or urge the formation of roots. The moist fibre preserves the correct humidity without the evil effects of too frequent watering and the most delicate and difficult plants can be grown quite easily.—G. R.

Propagation of Primula denticulata.

It is not generally known that this primula can be propagated from root cuttings. Pieces of root about 2ins. long should be inserted in pots of sandy compost with the tops level with the soil and placed in a moderate heat. This can be done now or in the spring and by the end of the first season quite large plants will have been produced. Where more than one bud is produced on a root they should be reduced to one.—L. T.

An Extra Half Guinea.

A hint well worth remembering at this season is that a year's subscription to THE GARDEN is a most suitable Christmas gift for your gardening friends. Not only will it provide them with pleasure, but will prove of immense practical use.—BRENDON P. MANSFIELD, 9, *Montrose Terrace, Ranelagh, Dublin.*

[We quite agree with this excellent suggestion It is well worth an extra half guinea.—ED.]

Propagating Perpetual Carnations.

This is the method I have found most successful with cuttings. Take good healthy growths from old plants. Strip off lower leaves, cut just below a joint with sharp knife, then split through joint, until you come to the next. I put cuttings in pure river sand, put through fine riddle if too coarse. Fill up as many thumb pots as required to hold three cuttings in each. Water sand previous to putting in cuttings, if too dry, as holes are easier made. Make holes round edge of pots with unsharpened end of pencil, as it makes a firm bottom for cuttings. Open split in cuttings with point of knife and insert in sand before putting in pots, and make cuttings quite firm. Label all pots and water and then put in propagating frame with very gentle bottom heat, and keep fairly close for a few days. Water only when required and open frame in mornings to dry up excessive moisture. I find cuttings root in about three weeks or a month. As soon as rooted pot up singly in thumb pots in good, fibrous loam and a dash of sand. I find that whereas nearly full percentage root in sand with cuttings split, I have been disappointed with cuttings cut just below a joint and in pure sand.—W. J. B.

A Firing Hint.

When sawing wood save all the sawdust possible (keep dry) and when sufficient has been saved, mix an equal quantity of clay or sticky loam and coal or coke dust, well wet and mix like mortar. Make a few moulds, 4ins. by 4ins. by 3ins. deep, with no bottoms and ram in the above mixture, leaving it to dry. These, when removed from the moulds, form bricks, which, if placed on the fire at night will keep the fire going until morning.

If tar is mixed with the above, this will make a good burning fuel for daytime use. It is advisable not to use the poker too much, also to warm the tar before mixing. These mixed with tar are also good for household use, care must be taken to pick out all stones.—H. M. B.

How to Get Early Greens.

Instead of pulling up the roots after savoy cabbage has been cut, strip off any decayed leaves and cut across each way of the top of the stalk and in a very short time they will begin to shoot out for greens. I have found them to be ready some time earlier than the curly or other greens. It is a great help if one has a small garden and being early they are over much before the spring planting.—T. W.

NURSERIES OF THE BRITISH ISLES.—VII

MESSRS. HEWITTS OF SOLIHULL.

THERE are hundreds of nurseries scattered up and down the British Isles which grow excellent plants for the general garden, and yet are unknown outside their immediate neighbourhood. The chief reason for this is that they do not specialise in any particular plant or group of plants. Once they begin to specialise their field automatically widens until they are known far and wide as growers of some special plant or plants.

A good example of this growth of a firm from a localised concern to one that is known throughout the country is Messrs. Hewitts of Solihull, Warwickshire. It is an old firm and was much respected in the neighbourhood; it was well known, also, in the district, for it owned several seed and flower shops in Birmingham. Only a very few years ago it changed ownership, when the policy was altered and, in addition to their local trade, they began to specialise in several well known plants, among them delphiniums.

As soon as one enters the nurseries one realises the importance that this firm places in delphiniums for the garden. A few years ago they were able to purchase the entire stock of some of Mr. Watkin Samuel's best delphiniums of the famous Wrexham strain. Although still to be classed as novelties and therefore, expensive, Messrs. Hewitt's are busily engaged in propagating them in

Digitized by Google

sufficient quantities to bring down the price to the limits of every gardener, and there is no doubt that they will succeed, for all that the writer has seen are worthy of being called great delphiniums. When we visited the nursery we saw row after row of the three that have already been propagated in quantity. The most striking, in our opinion, was Monarch of Wales, magnificent rows of plants with perfect spikes of that rich dark glow that comes from bright blue guard petals and a deep reddish mauve centre with a distinct white eye. The whole effect was so rich and glowing that it made it, in our eyes, a most notable plant. Coquette was another that took our fancy, enormous spikes of pale violet with blue markings and a dark bee-like eye. The third was Queen Mauve, a late variety and just bursting into bloom at the time of our visit, but such a fine mauve self and with such fine spikes that we could see what a garden plant it makes.

The great feature of the Wrexham delphiniums is the tapering spike and loose formation of their flowers. There is nothing tight and stiff about their appearance. We noticed this in Messrs. Hewitts' seedling beds, and particularly in one of their new seedlings, aptly named Advancement, which is one of the most magnificent garden flowers that we have yet seen. Unfortunately, it is not yet in commerce. The length of spike was nearly 6ft., of which 5ft. was in full flower. The guard petals are a clear electric blue with a pale mauve centre. The bottom of the flower spike was over a foot in diameter; and yet, with all its size, there is no more graceful delphinium. The flowers are beautifully spaced and are not too few to make the spike look ragged or too many to make it into a floral monstrosity. It has size and refinement, a very rare combination.

Solihull seems to suit delphiniums admirably. The cultivation that we saw was excellent, not only of the rarer and more expensive varieties, but also of such favourites as Mrs. Townley Parker, Blue Boy and Norah Ferguson; but the Wrexham delphiniums are the glory of the garden, and in time they will undoubtedly become everybody's plant.

It is not only with delphiniums that Messrs. Hewitts are coming to the fore. Roses are being grown more and more by this firm, and those that we saw were admirable specimens that showed what care had been taken over their cultivation. Then, gladioli and astilbes are other specialities. This firm believes in the future of the primulinus hybrid as being more refined in appearance than the large-flowered, popular though the latter is. Their collection of astilbes is very complete and proves that this plant is increasing in popularity every year. This is only a tithe of the plants grown. There are fine collections of general herbaceous plants and shrubs to look at if you have the time. This is a most interesting nursery to visit. It is not too large, and so the directors can superintend personally everything that goes on. Also, the soil and climate are similar to those of many thousands of gardens; so conditions are equal, and gardeners may rest assured that the plants are given ordinary treatment. This makes them succeed in any garden.

A NURSERY BED OF DELPHINIUM MONARCH OF WALES, A MOST STRIKING VARIETY.

OUR SERVICE BUREAU

Though so many subjects are dealt with in each issue of THE GARDEN, *it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, there is always information available from a staff of expert contributors and consultants; and there is no charge for this. It is one of the additional means of service which* THE GARDEN *is glad to render to its readers.*

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope and the coupon, that will always be found in each issue, shall be sent with the enquiry. We would point out, however, that we cannot undertake to supply readers with plans and designs of gardens, but will willingly assist in giving suggestions for planting.

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2.*

We have selected the following enquiries, with their answers, as being of more general interest, and therefore worthy of publication.

A Remedy for Pear Scab.

As a constant reader of THE GARDEN *for over twenty years I should be much obliged if you would tell me of a sure remedy for black spot on the fruit of pear trees.—J. W. R., Leatherhead.*

The black spotting on pear fruits is, of course, caused by the pear scab fungus disease, and the remedy for this is spraying with Bordeaux mixture in spring. Spray with this, once just before the petals unfold, and a second time when the petals have all fallen. This disease is wintering on the wood of the trees, and you can recognise infected shoots by the blistering of the bark. Such shoots should be cut away at pruning time. We should recommend you to buy a good brand of Bordeaux mixture for the spraying rather than attempting to make it at home, for its efficiency depends upon the scientific accuracy with which the wash is prepared.

How to Deal with Ferns Attacked by Scale.

I enclose the frond of a fern attacked by scale. The fern is grown in a large pot kept indoors. It has been repotted once or twice, all attacked fronds cut off and treated with turpentine, but the scale keeps reappearing. What should I do with it? What is the name of the fern, and is it hardy? If so, I propose to plant it out. Can I safely add some Vaporite to its soil?—C. A. W., Stevenage.

The fern sent for our inspecion is Pteris tremula, a greenhouse species, and not hardy in this country. The only way to keep the scale in check is by frequent spongings, using soft soap dissolved in warm water for this purpose, but it will require constant attention. Unfortunately, scale is a serious pest on many plants in this country. You could add Vaporite to the potting soil, but it would not be wise to use it for a week or so after mixing with the soil. If you give it directly to the plants, you would probably injure the roots; in any case, it does not seem necessary, as it will not prevent the scale.

How to Treat a Steep Bank.

My new house stands some 8ft. above the level of the front garden, and faces north-east and is slightly sheltered. Would a dry wall be successful in this position? If made, the wall would be about 20ft. from the house front and parallel to the house, and would get morning sun, but would be in the shade late in the afternoon. My frontage to a road is 60ft. If you do not think a dry wall would be a success, kindly suggest another treatment. I want to keep away from a grass bank. The bank is too steep for the mower. Kindly suggest best stone for a dry wall and, roughly, the amount I would require, i.e., a wall 60ft.

Digitized by Google

long and, say, 6ft. high. I had thought of planting the bank with shrubs so as to conceal the house, and construct a rockery in the garden below. Then one side —60ft.—would be open to the road. I am enclosed on both sides by tall chestnut trees—almost woods.—C. U., Canterbury.

Rather than the dry wall and rockery below, we suggest that the bank is treated as a rock garden which would run out, generally, half way along the level portion of the garden. Adjoining the road there should be a shrubbery border 7ft. to 9ft. wide to provide privacy and shelter from the north-east winds. Between this border and the outcroppings of the rockery there should be grass, with an occasional low-growing shrub. The line of the bank should be broken at irregular intervals, and this would provide soil for filling the angle, to prevent an undesired hiatus.

American Gooseberry Mildew and How to Check It.

Could you name anything which acts as a real check to American gooseberry mildew? Are there any varieties which show less inclination to become affected?—G. G., Bangor, North Wales.

The best means of checking the spread of the American gooseberry mildew is to spray the bushes at the onset of the disease, in early summer, with the Ammonium Poly Sulphide wash, commonly known as the "A.P.S." wash. A reliable brand of this is made by Messrs. Murphy and Son, Limited, The Cedars Laboratory, Mortlake, S.W.14. There are no varieties that are immune to this disease and few less susceptible than others, but Cousen's Seedling, sometimes known as Sandwich Yellow, seems far less liable to attack than do most others. This variety is a large golden-berried sort and among the latest to ripen; quite worthy of a place in any garden. You should note that another remedial measure for the mildew is to "tip" the shoots in early autumn each year. It is mostly the tips of the shoots that are attacked, and it is a good plan to go over the bushes in early September and cut off the top 2ins. or 3ins. of every shoot on a mildewed bush. If the "tipping" is left later, the spores of the disease fall to the ground and infect the soil, from which source re-infection takes place in spring. Regular "tipping" and thorough spraying with the A.P.S. wash, as required, will not fail to keep the disease in check.

Manure for Fruit Trees.

I should be much obliged for advice with regard to manure for apple trees, also pears. The trees are young standard ones, planted in 1918. Is it best to give them manure in autumn or spring? One has the choice between horse manure, poor stuff nowadays, or bone meal, or hop manure, or guano, but which of these is most suitable? How and when are they best applied, and in what quantities?—P. T., Streatham.

Just what will be the best manures to apply to the apple and pear trees depends rather upon the soil and the vigour of the trees. As your garden soil is poor and heavy, we would first suggest the application of lime. Slaked lime, applied at the rate of about ½lb. per square yard, will be best, and it might be forked lightly into the top soil towards the end of the month. Horse manure will hardly be required on such land, except as a surface mulch for the trees. Phosphates will no doubt be lacking in the soil and we should advise an immediate dressing of basic slag at the rate of about 6oz. per square yard of ground about the trees. This is cheaper than bone-meal and much more suitable for your land. Then, if the trees are not growing well and are stunted in growth, we would also apply a dressing of sulphate of ammonia, in March, at the rate of about 2 oz. per square yard, but if they are growing healthily and fairly strongly, this dressing will be unnecessary. The surface mulch of horse manure should be laid on the soil round the trees some time in late April or early May, and should be gradually worked into the soil toward the end of summer. Later, when the trees are cropping, a dressing of kainit every few years, at the rate of about 4 oz. per square yard will help them along. It should go on in late winter. The guano is a very variable manure and unless the trees are very weakly in growth we would not advise its application. As a general rule, young standards require little in the way of manure, and until they commence to fruit heavily a biennial dressing of basic slag and a summertime mulch of manure will usually supply their needs.

Plums and Silver Leaf.

I have had some plum trees grubbed up and burnt, which were affected with "silver leaf," and wish to plant new ones in the same place against a wall. Would the new trees be liable to infection by being planted in the same place?—B. T., Bembridge, Isle of Wight.

If it is possible to plant the new plum trees between the positions that were occupied by the diseased trees—now grubbed—then it would be by far the safest plan to adopt. The danger of the new trees becoming infected through the soil, or from pieces of old root left behind is, actually, very slight indeed, but it is hardly worth while taking that small risk, even. If it is impossible to avoid planting on the site of the old trees, then we recommend that the old soil be taken out where each tree is to be planted, to a depth of 2ft. or 3ft. or so, and replaced with fresh, or good soil taken from another part of the garden. Care should be taken to leave no pieces of root in the soil when grubbing, and it would be as well to incorporate a fair dressing of lime in the soil border. You will know that the silver leaf disease can only spread from dead wood and can only enter healthy tissues through a wound or abrasion of some kind or other, so that if care is taken the new trees should be in no danger of contracting the disease.

How to Remove Old Tree Stumps.

I shall be glad if you will kindly give me directions for getting rid of old tree stumps without digging them out, which takes such a long time. Some of the stumps are rather rotten, others the wood is quite hard.—K. S., Turriff, N.B.

Where the stump is partly decayed and is beginning to crack, there is no better plan than to pour into the openings a pint or more of paraffin. This rapidly soaks into the wood and, on the following day, a fire should be set going of any dry rubbish on the top of the stump. In quite a short while the stump and most of the big roots will have been reduced to ashes. If the stump is not rotten, but the wood has had time to get rid of its sap, the following is the best method of procedure: Get some old pieces of sheet iron and bend them round to form a rough chimney. The iron may be held in place by a few stout stakes and the lower part of the chimney should be rested on two or three bricks, so that there is a space between it and the top of the stump. Bore a few holes in the stump and then pour in paraffin. Set the oil-soaked wood on fire and a very fierce blaze will start roaring up the chimney. this will continue until the greater part of the stump has been destroyed.

When a tree has only just been cut down, the stump will naturally contain a great deal of sap. In such a case, if complete destruction of both stump and roots is desired, the method known as "slow-fire" is strongly to be recommended. Here bore a hole in the centre of the stump one or two inches in diameter and about 18ins. deep. Put into this about a couple of ounces of saltpetre and then fill up with water, finally plugging closely. Leave for as long as possible, several weeks or even longer is not too much, and then take out the plug and fill up the hole with paraffin. Ignite the wood at the top of the opening and the stump will smoulder away without any fierce burning. The burning will continue until every part which was penetrated by the saltpetre solution has been consumed. The fresher the wood the greater is the success of this plan, as the more sap there is in the wood the more widely is the saltpetre solution distributed.

Lonicera nitida as a Hedge Plant.

I should be very much obliged if you can tell me whether a hedge of Lonicera nitida is likely to grow well on gravel soil in a situation exposed to south-west gales, protected from east and north winds. I believe it makes a good hedge and grows fast.—W. M., Leics.

Lonicera nitida is an excellent hedge plant, and should grow well in the position which you suggest for it. If possible, fair-sized plants should be obtained, in order that a close hedge may be formed fairly rapidly. The individual plants should be put in about 2ft. 6ins. to 3ft. apart.

Treatment of Lilium Regale When Young.

I should be glad if you would advise me as to the treatment of some small bulbs of Lilium Regale. I have several hundred of these bulbs grown from seed sown last February. The bulbs are now about the size of a cherry with strong fleshy roots. I have taken a few of them up and dried them off. Is it best to do this and replant in the spring or leave them in the ground until the spring and then replant? They will have to be replanted some time as, of course, they are in a nursery bed fairly close together.—A. T. M., Leatherhead.

It was a mistake to lift the small bulbs of Lilium regale and dry them off, as they are too small to stand drying off. You should put them in boxes of light sandy soil and keep them in a cold frame all the winter, keeping them on the dry side until spring, when you may plant them outdoors. Leave the other seedlings undisturbed until spring, transplanting them before they commence to grow. Prepare a special site for them, working in plenty of well decayed leaf-soil. If you can plant them where you wish them to remain you should get the best results, for most liliums resent being moved, especially when the bulbs have attained some size.

How to Make an Asparagus Bed.

Will you please tell me how to make an asparagus bed, when to plant, etc.?—H. S. P., Brondesbury, N.W.

When the weather is fine and the soil dry enough, the latter should be trenched at least 2ft. 6ins. deep. If the ground is level, form beds 5ft. wide to accommodate three rows of plants. Provide alleys between the beds each 18ins. wide. Raise the beds a little by taking soil from the alleys. Plant as soon as the soil is dry enough to work nicely in March. Put in two year old plants about 1ft. apart in the rows and cover the crowns with soil 4ins. deep. Water, allow free growth all summer, and do not cut any "grass" the first year. Feed mainly from the surface.

NNELL & SONS, Lincoln
Established 1780.

PROPRIETARY MANURES.

Quick-Acting Stimulants.

WITH nearly all compound manures their constituents and directions for use are given by the manufacturers, and purchasers should duly note such directions and follow them carefully. All of these manures are carefully prepared, too, tested and recommended for certain plants and crops. I do not intend to refer to these manures further now. But there are several quick-acting stimulants which, rightly used, are very beneficial to plant life and, wrongly used, prove deadly because they destroy the roots. Sulphate of ammonia is very commonly used in our gardens. It is a valuable stimulant if used for pot plants when the latter have fairly well filled the soil in the pots with roots. Used in a dry state a small teaspoonful to a 9in. or 10in. pot will be sufficient. In a liquid form ½oz. to 3 gallons of water. When potatoes are planted, 1 oz. per 3yds. of row, and a similar application just before the potatoes are earthed up will do nicely. Rarely is it necessary to apply more than three dressings to any plant in one season. One application is enough for chrysanthemums. Peaty soils, and others practically devoid of lime, are not rooting mediums in which sulphate of ammonia can be profitably used. It readily dissolves and quickly becomes a soluble plant stimulant. Nitrate of soda is, perhaps, quicker in its effect on plant life. It is not retained in the soil and should be used in small quantities several times rather than in strong doses seldom. One pound per 50 sq. yds. will be sufficient. For dwarf and runner beans it is very good, adding to the colour and tenderness of the pods as well as promoting rapid growth of stem, leaf and pod. Nitrate of potash should be more freely used—in weak doses, of course—for indoor greenhouse and conservatory plants in pots and borders. For tomatoes it is very useful and helps in the high colouring of the fruits. Sulphate of potash can be similarly used, also wood ashes in a dry state. Phosphate of potash, applied in liquid form, at the rate of 1 oz. to 3 gallons of water, will do a lot of good to vines, peaches, apricots, nectarines under glass and to fruit trees outside. When used for pot-grown plants the strength should be reduced to half.—G. G.

PUBLICATION RECEIVED.

"Research and the Land." (Published by H.M. Stationery Office, price 2s. 6d.)—A popular review of the whole field of scientific research in agriculture and horticulture in the United Kingdom. This work summarises and presents in an interesting form all the technical investigations that have been carried out during the past four or five years at research institutes and other centres where research is conducted. It is a book which all who are interested in the land should possess.

R.H.S. EXAMINATIONS.

THE examinations of the Royal Horticultural Society will be held in 1927 as follows:

Written Examinations.—General Examination (Seniors and Juniors), Wednesday, March 23rd. School Teachers Examination (Preliminary and Honours), Saturday, March 26th. National Diploma (Preliminary and Final), Saturday, May 7th.

Practical Examinations. — Teachers' Honours, Friday, June 17th and possibly also Thursday, June 16th. National Diploma, Preliminary, Tuesday June 21st and Wednesday, June 22nd. Final, Thursday, June 23rd and Friday June 24th.

All entries, except those for the National Diploma, should be made on the form in the syllabus, obtainable from the Secretary of the Royal Horticultural Society.

WAKELEY'S Celebrated Hop Manure

(PATENTED)

THE ORIGINAL AND ONLY RELIABLE SUBSTITUTE FOR STABLE MANURE

AS USED IN THE GARDENS OF GREAT BRITAIN

DIPLOMA AND MEDAL, ROYAL INTERNATIONAL HORTICULTURAL EXHIBITION, 1912

DO YOU REALISE IT?

A large bag of WAKELEY'S PATENTED HOP MANURE at a cost of only 7/- carriage paid to your door (if within 25 miles radius of London, or at a trifling extra if beyond), GOES AS FAR AS A CART-LOAD OF STABLE MANURE, without any of the defects of the latter; gives better results, is easy and clean to use.

Every ounce of Wakeley's Hop Manure is of value to the soil, supplying the necessary HUMUS in addition to the valuable plant food. Worthless rubbish is not added to make weight (as is the case of some artificial manures advertised).

Thousands do realise it, the proof of this is the constant flow of UNSOLICITED LETTERS received from time to time in praise of the wonderful results obtained at such a moderate cost (see Booklet for selection).

BEWARE OF IMITATIONS.—Genuine Only in our Marked Bags containing Guaranteed Analysis.

Just a post card, and our Catalogue of Bulbs and Garden Sundries at carriage paid prices will be sent free.

CASH PRICES (including bags):

Small (about 1 bushel)	3/-
Large (about 4 bushels)	7/-
5 Large	33/9
10 Large	65/-
20 Large	120/-

Carriage paid by Pickford's or to any station within 25 miles of London, including delivery if within free delivery radius of Railway Company; 6d. per bag extra for every 50 miles or part beyond. Maximum extra charge Great Britain, 2/6 per bag.

THE GARDEN

VOL. XC.—No. 2869. NOVEMBER 27, 1926. PRICE TWOPENCE.

NOTES OF THE WEEK.

Garden Crops for Next Season.

THE importance of looking forward to the seasons when garden crops will yield their produce cannot be overestimated, since it is by no means difficult to obtain a practically unbroken supply of certain varieties all the year round by the exercise of judicious foresight in making successional sowings and planting out seedlings in batches at different times in varying aspects.

Systematic cropping also is of great importance, and arrangements should now be made for the ensuing season's crops. A good idea is to make a plan by marking out on a sheet of paper the quarters or divisions of the garden. This very much simplifies matters when the actual sowing and planting takes place. The plots can be manured and treated exactly as their requirements demand, and in the long winter evenings this plan-making is a good form of recreation to the man who is fond of his garden.

A kitchen garden can be made both productive and attractive, be it either small or large, by some thought and perseverance. It is not the man who has the best garden that always wins prizes, but the one who studies his crops from start to finish. There are plenty of good growers who could win prizes, but on account of neatness and love of method they do not like interfering with their crops, which they must do if they exhibit.

Of course, in plotting and planning for his spring planting the gardener will be guided to a great extent by the nature of the crops he is clearing off the ground at the present time. Where he has grown his celery would be a capital place for green peas or a root crop, such as carrots, turnips or radishes. Having decided on this, he can save himself a lot of labour by a systematic method of lifting the celery. To do it properly and leave the ground in an even and workable state, commence at one end of the row and, level down the soil at the sides of the celery with a fork, at the same time digging or forking the ground over. The celery should be lifted with a fork, and the manure in the trench should be spread out on the surface to be forked in again. By doing this the ground is left in a clean and healthy state, and in fit condition for the next crop.

Light crops, as lettuce, early peas and early cauliflowers, may well follow the roots, and such quick-growing subjects as lettuce, radishes and summer spinach may come after the first early potatoes. Little or no manure will be necessary on these plots. The space allotted to turnips must be well enriched before again cropping it—a good dressing of soot or lime is very beneficial after such crops.

Every gardener should scheme out the whole of his ground if he wants to make the best of the space at his command, and cultivators who would secure the best results ought not to overlook the following simple facts, *i.e.*, lands which are heavy, tenacious and turn up lumpy should be surface forked when fairly dry some days after they are first dug and have been exposed. Light, sandy or stony soils are best dug a few weeks before crops are committed to them, so that they settle down and, by natural cohesion, make a sufficiently firm bed for root growth. Moreover, for small seeds the surface of the ground cannot be too finely broken.

A Gladiolus Guide Book.

SUCH is the title of a fourteen page booklet which reached us from Canada a few weeks ago. The first page contains the Index, from which we find that such matters as "Best Varieties by Colour Sections," "Notes on Culture," "Gladiolus Diseases," and "The Present and Future Gladiolus," are some of those dealt with in its pages.

Dean Herbert, who was an enthusiastic cultivator of the gladiolus, wrote, in 1820: "I am persuaded that the African Gladioli will become great favourites with florists, when their beauty in the open border, the facility of their culture, and the endless variety which may be produced from seed by blending the several species, are fully known."

Notwithstanding that Dean Herbert wrote the above over a hundred years ago, the writer of this booklet states: "Improvement of the Gladiolus is only well begun and I confidently predict that the next few years will see such grace and refinement added to this popular flower as to rival the Iris and the Orchid in beauty of form and colour."

The best varieties list is a feature which will appeal not only to the novice, but also to the older gladiolus growers. It is well up to date and is arranged in no fewer then twenty-four colour sections. Then we have the general variety list, and here again we are helped in our selection for special purposes, such as Exhibition, Commercial, Garden or Landscape, the best in each section being given five marks: thus, we have the variety A. W. Hunt marked, for exhibition, 4; commercial, 5; and garden, 5. The gladiolus for landscape purposes may be said to be a very recent use, therefore we may quote from page 7: "These are of medium height, with small or medium flowers in bright or strong colours and with a long blooming period." The varieties receiving full marks in this section are Alice Tiplady, Anna Eberius, Butterboy, E. J. Shaylor, Golden Gleam, Mr. Mark, Orange Brilliant, Souvenir and Sulphur Glow.

The notes on gladiolus diseases are prefaced by the statement: "Gladiolus has been so little troubled by disease that growers have become careless and we now have, more or less infection as the result."

A full page of notes on culture brings this very useful list to an end, and it only remains to us to mention that it is from the pen of Professor J. W. Crow, Simcoe, Ontario, Canada.

HAVE YOU

¶ *Protected your tea roses with some light litter?*

¶ *Staked securely your newly planted trees and shrubs?*

¶ *Trained, pruned and nailed up all creepers on walls?*

¶ *Pruned your apricots and cherries?*

¶ *Cleared away the faded stalks of your late-flowering herbaceous perennials and given your border a dressing of bone meal at the rate of 4 oz. per square yard?*

¶ *Examined and cleaned out your land drains and soak-aways?*

¶ *Sprayed with caustic soda solution your moss-covered fruit trees?*

¶ *Applied a soil fumigant to soil infested with wireworm and leather jacket grubs?*

The Crossword Prize.

THE prize of Two Guineas offered to the reader who sent in the correct solution to THE GARDEN Crossword Puzzle No. 1, which appeared in our issue of November 13th, has been awarded to MRS. BOULTON, Chorleywood Lodge, Nr. Watford, Herts, whose solution was the first correct one to be opened, and to whom a cheque for that amount has been sent.

PLANNING AND PLANTING A SMALL BORDER

This border plan and the accompanying planting suggestions will be found suitable for a space such as may be found in many villa gardens throughout the country.

FOR some time I have been trying to puzzle out a more or less satisfactory method of planting the small border so often found in villa gardens.

It is comparatively easy to deal with a border 10ft. to 15ft. in width and 80ft. to 100ft. or 150ft. in length, because there is room for mass and colour planting, as well as a varied choice of material. But the restricted area of the villa border calls for an equally restricted scheme of planting, necessitating heart-rending sacrifices of fugacious favourites, if the ground is to be kept furnished for the summer season, and not entirely unsightly for the rest of the gardening year.

I have come to the conclusion that the main groupings in a border, roughly 8ft. by 40ft., must be of such plants as keep their character to a great extent all through the year, interspersed with those flowering subjects which hold their bloom for some weeks in succession; anything of a less lasting nature must be found a place elsewhere.

In the first class I include chiefly grey-leaved plants and shrubs, such as Santolina incana, pinks, helianthemum, Stachys lanata, Dwarf lavender (although this looks somewhat woe-begone in wet weather) and some of the artemisias: in the latter class, delphiniums (absolutely indispensable), Linum perenne, hollyhocks, Michaelmas daisies, Iris pallida, erigerons, anthemis, or Coreopsis verticillata, polyantha roses and a few annuals. Certain bulbs, such as Madonna lilies and May-flowering tulips, should certainly be included. All these plants and bulbs are hardy, will grow anywhere with the minimum of care, and are inexpensive: the only "doubtfuls" being the hollyhocks and the lilies, both more liable to disease than any of the others.

The accompanying planting plan gives an idea of the scheme: but where there are double borders the colouring in the second one could be varied by using different varieties of the flowering plants shown in No. 1, also by replacing some of the grey foliage by small specimens of carefully chosen gold privet and other herbs and plants with yellow leafage.

I regard Santolina incana as the most useful of the "backbone" plants. It is good-natured always—save for a very brief period when cut back in the spring—well furnished, thrifty, tidy, and oblivious to the vagaries of the weather in its personal appearance. Next to this I place Stachys lanata, although, like the dwarf lavenders, Munstead, Wargrave and Nana, it does not look absolutely happy in saturating rains: but it provides such velvety white leaf masses that it cannot be done without.

Both the silvery artemisias I know as A. Ludviciana and A. Palmeri are graceful need no introduction from my pen. The silver thyme is delightful in leaf, flower and fragrance.

The one helianthemum mentioned is Rodanthe, which makes a close mound of grey foliage smothered with large salmon pink flowers for several weeks in succession, and provides a welcome mass of this rather scarce colour. Iris pallida takes its place among these furnishing plants by virtue of its lovely orchid flowers and handsome, sword-like, lasting leaves.

The flowering groups are chiefly composed of the "daisy" type of plant, because no other family seems to bloom so profusely or continuously. Erigeron Quakeress and Anthemis E. C. Buxton remain in flower for nearly three months, while Linum perenne makes an excellent third, with the added merit of differing growth and blossom.

I could not bring myself to leave Lilium candidum out of any ground I had to plant, be it only a square yard or a million; but others may be harder-hearted and dispense in early leafage and later inflorescence: while Pink Her Majesty or Allwoodii Harold with this somewhat capricious beauty. The other bulbs I should tuck in wherever possible would be the Darwin tulips Clara Butt and Mrs. Moon, both charming in colour, long-lasting, accommodating and cheap.

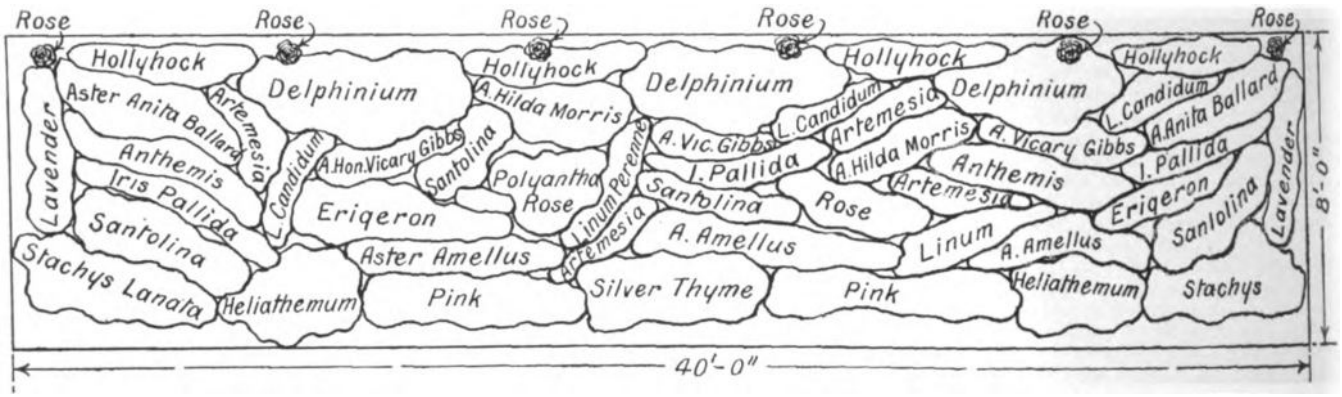
Among the taller subjects I have included clumps of hollyhocks, although here lies very possible disappointment owing to "rust": but it is worth while trying to persuade these stately beauties to grace the garden with their lovely frilly faces: and for late summer flowering those charming perennial asters, Anita Ballard and Hilda Morris (the latter not new, but most excellent).

Asters Amellus Beauty of Ronsdorf and King George are indispensable for second-row planting: they are compact, of medium height, and bear quantities of large mauve and purple daisy flowers. A. ericoides Hon. Vicary Gibbs should be planted in front of the delphiniums to cast its delicate mauve veil before their derelict remains.

I hesitate to name varieties of these self-same delphiniums. So much depends on personal inclination and depth of purse: but for myself, I think Willy O'Breen, Amos Perry and Smoke of War pleasant both to the eye and the pocket. If one is lucky enough to have a duplicate border waiting to be filled, well! there is an opportunity for wider choice lurking in every catalogue.

The rose pillars are of the nature of a problem, as the flowering period of the Wichuraiana and multiflora roses is too brief, and the pillar roses somewhat erratic in their climbing capacities. Climbing Mme. Abel Chatenay and Climbing Ophelia flower continuously with me, and so do the Dijon teas. Emily Gray is charming where it flourishes, and Mermaid might be tried in a congenial climate. The Garland rose is excellent and might be combined with Clematis Flammula. I should choose the polyantha roses Coral Cluster and Juliana for the beauty of their soft salmon colouring in the border itself.

I have mentioned annuals to fill the smaller gaps. Of these I should include a soft salmon antirrhinum, such as Rose Doré, the forget-me-not-like blue nemesia, the lemon African marigold and the pink and mauve annual scabious, according to the height required, and where they will best fit into the general colour scheme.



It will be noticed that the colour scheme is on the same restricted scale as the variety of plants: but there is no room in such a small space for flowers of red, bright yellow or purple colouring, although this entails the sacrifice of the many good plants bearing them.

C. E. A.

THE VARIEGATED ARABIS.

THE old form of Arabis albida, with downy leaves and bearing in spring and early summer such a profusion of white flowers as to be known familiarly as "Snow on the Mountain," has been so often recommended as suitable for a rock garden that one scarcely likes to utter a word of deprecation concerning it. This much can be said, however: that, unless it is kept strictly within bounds, it is apt to become more of a nuisance than otherwise, usurping space which of right belongs to choicer and better plants; but as a plant for draping a rough stone wall, it has, like the aubrietia, its uses. I have noticed those who commence planting a rock garden often plant the arabis as a first tenant, but after a time dispense with it; and the only conclusion I can come to is that its almost irrepressible habit has led to it being superseded. My experience of the variegated form of arabis is somewhat different, as I find it to be rather more compact of growth and not given to rambling to the same extent as the older sort, and I wonder whether I am alone in my surmise that it is more useful in a garden because of this? It makes a convenient edging for a border; may be used as a foreground for bulbs; strikes easily from cuttings after it has flowered, if inserted in sandy soil; and, what is equally important to be noted, I think, is "cheerful-looking" at all seasons, if I may use such a term, owing to its variegated foliage.—CLAREMONT.

SHRUBS FOR DRY BANKS

Many readers have dry banks in their gardens which they may have some difficulty in treating satisfactorily. In this article they will gain much information on what to plant where the soil is arid and watering a difficulty.

IT has been my lot for a good many years to deal with very dry, sloping ground and banks of poor soil. Owing to the contour of the land, trenching and manuring were practically impossible. The shrubs had to be put direct into the soil with a minimum of preparation, and watering was out of the question. Yet, a great measure of success has been attained, largely due to a selection of the right subjects.

The brooms and genistas all rank high as dry land subjects and with them the planter can scarcely go wrong, provided he takes due note of the sizes of the various species and selects according to the area of the space to be covered. Members of the Cytisus group which I have found most suitable where nothing very tall is desired, include the beautiful C. præcox, C. purgans, one of its parents, with flowers of a very rich yellow and deliciously fragrant; C. nigricans, for late blooming; the prostrate C. decumbens, C. Beani and C. kewensis. In taller kinds one may indulge his fancy to almost any extent in the various forms and hybrids of the C. scoparius set. C. albus, the white broom, is a singularly lovely species, easily raised from seed.

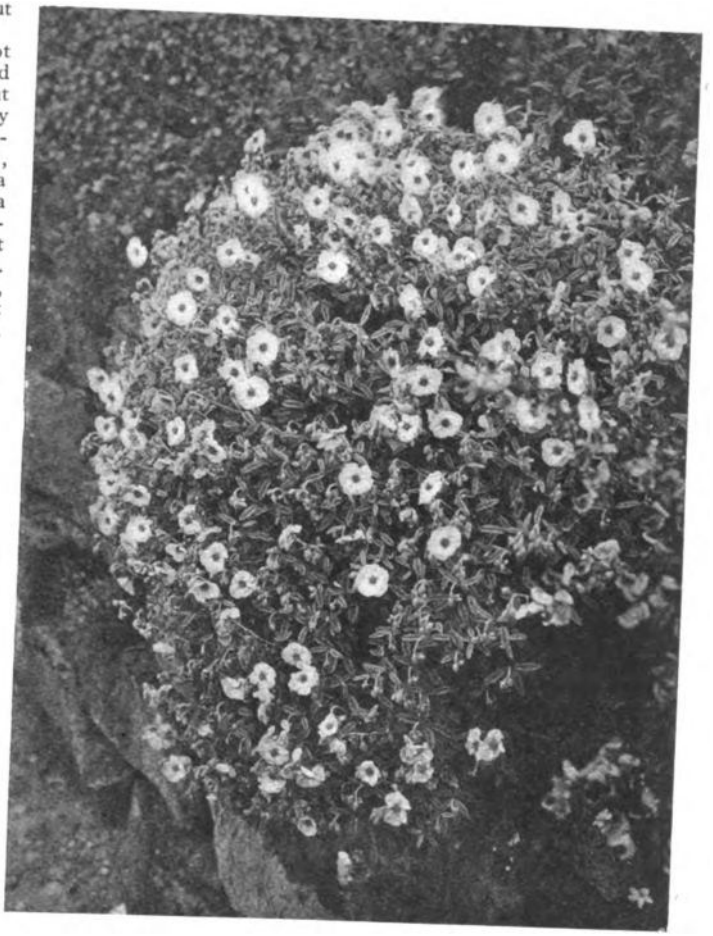
Genistas.

Genista cinerea and G. virgata are, perhaps, the best of the taller kinds in their genus, most elegant, silvery-leaved shrubs which are clouded with golden-yellow blossoms in early summer. G. tinctoria in all its forms is invaluable for late flowering, the dwarf, double-flowered variety being excellent for grouping with such more or less prostrate kinds as G. sagittalis, G. pilosa, G. hispanica (this is better than G. germanica), and others of which the lists are eloquent. Near to these come the double gorse, one of the most magnificent shrubs known for the purpose in view. Though all the above have a reputation for moving badly I never find any difficulty in planting from pots, in which they are usually supplied. As for the taller kinds, if these are put in fairly young, say 2ft. high, they will rarely fail if the main stem is cut back about half way at the time.

The heaths are not generally considered dry ground plants, but Erica cinerea certainly does well in most sun-burned, rocky places, and both Calluna vulgaris and E. carnea can be tried wheresoever conditions are not quite so severe. The first mentioned, notably such excellent varieties as E. c. rosea, atrosanguinea and the dwarf coccinea, I have established under most arid conditions, care being taken to plant deep (that is, well up to the foliage), and a little leaf-mould being put around the roots to give them a start. Where the slopes are steep these and other dwarf shrubs are planted in holes made more or less laterally, and if their first summer should be hot and dry some bracken or hedge brushings are strewn over them to help to retain moisture.

Rock and Sun Roses.

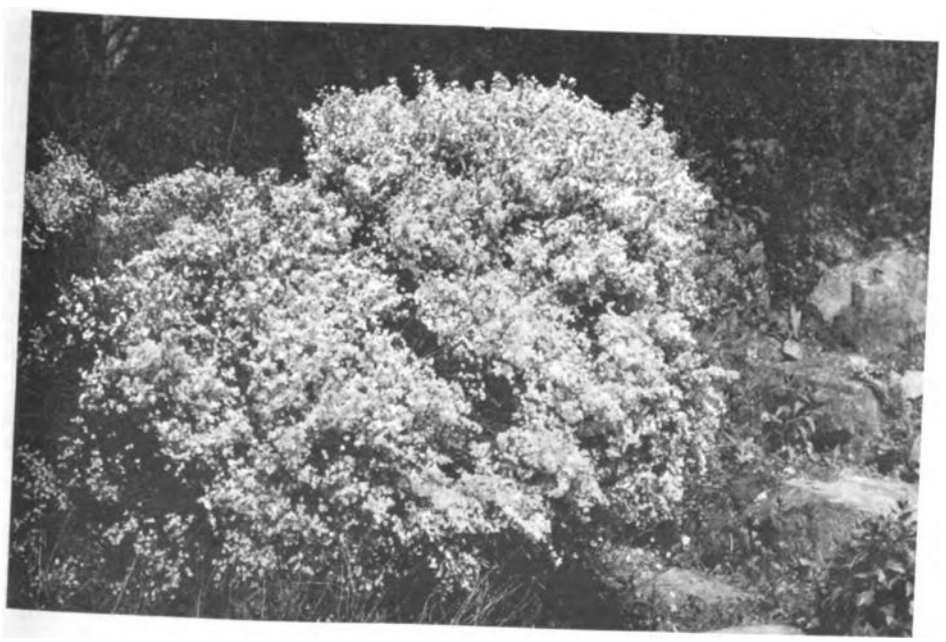
All the cistuses and helianthemums are good subjects for sun-beaten, thin soil, and those whose climate will allow them to grow these charming shrubs need not hesitate in making a wide choice. Of the former C. cyprius and C. Loreti are the hardiest and best of the medium-sized kinds and these are generally long-lived and vigorous. Then come the lavenders and rosemary.



SUN ROSES ARE INVALUABLE FOR DRY BANKS.

Whether associated with the bell-heather, the lesser brooms or anything else of kindred nature, there can be nothing lovelier on a sunny, hot slope than the Burnet roses (Rosa spinosissima). These include the Scotch roses in various colours, the little bronzy type species with fragrant cream or pink flowers, var. lutea which grows to 3ft. and bears large blooms of a full-toned yellow and others. R. alpina, with pea-green foliage, thornless branches and crimson blossoms, is also a most useful and engaging little rose of 3ft. to 4ft. for the present purpose. Nor can we omit our own sweet briar, and where something bigger is desired, the Ramanas roses (R. rugosa) will prove very amenable even in exceedingly dry and sandy, or rocky, conditions. Associated with these last, Spartium junceum is a well tried, fine old shrub of the utmost reliability in the driest of places, especially if planted as seedlings and cut half way back when about 2ft. high. The trailing roses of the Wichuraiana class are excellent for covering banks, many of them retaining the prostrate habit of the type,

All the more or less procumbent cotoneasters, especially C. congesta, C. humifusa, C. adpressa and the flat growing forms of C. horizontalis, are admirable subjects for steep banks of dry, poor soils. They grow fast and in addition to their natural beauty of form and foliage, afford striking autumn tints of berry and leaf. A. T. JOHNSON.



CYTISUS PURGANS, A WEALTH OF SWEETLY SCENTED GOLDEN FLOWERS.

IN THE GREENHOUSE

Roof Plants in Conservatories.

I DARESAY that many readers of THE GARDEN will have noticed how plants were growing under the glass roofs of conservatories when visiting their friends. Quite 90 per cent. are allowed to cover the whole of that portion of the roof allotted to them. It is too true that roof plants are so treated—to their own detriment as well as the plants growing in the body of the structure. The reason is natural growth, and lack of formal training. But there must be a certain amount of formal training in a confined space when we are dealing with large-growing kinds of plants. Much the best plan is to train the main stems at so many feet apart to strong wires or rods and to allow the small, or side, lateral shoots some freedom, which takes away any formal appearance as a whole. The system is somewhat similar to that of grape vine training. Climbers so treated generally thrive well and also the plants growing under them—light and shade being well balanced. There is no better time than the present for making arrangements for the furnishing of the roofs of conservatories, and these hints should be borne in mind by the inexperienced when carrying out the work. Afterwards, when it is necessary to prune, tie or clean the climbers, their proper arrangement will enable the owner to attend to all the details easily, and the work will be a pleasure rather than an irksome duty. New plants should be planted in good fibrous loam, this forming the bulk of the compost. A small proportion of leaf-soil will be suitable for the majority of these plants and peat for a few. The following are lovely roof plants: jasminum, Bougainvillea glabra, plumbago (white and blue), heliotrope, tacsonia (passion flower), Lapagerias rosea and alba, Cobæa scandens and the variegated variety.—G. G.

Forcing Azaleas and Rhododendrons.

WELL grown plants bear many flowers and they have a charming effect in a conservatory or greenhouse during the early spring months. By well grown plants I mean those specimens that have been grown in pots at least one year. Azalea mollis, and also A. indica, may be potted and forced at once, but the plants, afterwards, owing to the undue strain put upon them, take a long time to regain their normal condition. The plants, prior to being subjected to heat, are usually kept on a bed of ashes, outside, with ashes tightly packed between the pots to prevent the latter and the roots inside them being unduly frozen. When first introduced to a forcing temperature the latter should be a mild one—about 55 to 60 degrees. Indeed, only in exceptional cases is it necessary to have a much higher temperature. An ideal temperature and atmosphere will be found in a newly started vinery. But all growers of these flowers do not possess a vinery. First, be sure that the drainage is free and the ball of soil thoroughly moistened through with clear water. Clear water is the safest to apply till the flowers have faded. It should be remembered that the new shoots of these plants appear as the buds develop and finish their growth, almost by midsummer. Established plants should be repotted, if they need it, soon after the flowers have faded, so that they can be syringed and treated under glass till they are removed to frames and then the open air again late in June. The next batch of flower buds form from the latter date on suitable shoots.—HANTS.

Winter Treatment of Perpetual Carnations.

OUT of much tribulation have the growers in northern districts learned that the perpetual tree carnation can only be grown successfully by striking the cuttings in early autumn. Winter cuttings, by reason of their surroundings, become etiolated and lack the robust ripeness that a cutting capable of making a good plant should have, and are a bother and a disappointment from first to last.

The cuttings put in by late September should now be sufficiently well rooted to require their first potting. There are various opinions expressed regarding a suitable soil for this potting; and a visit to some of the most eminent growers does not enlighten us much, as there we find them using a composition consisting of the residue from large fires in which a considerable quantity of soil would be burnt.

The efficacy of this medium is beyond question, but we do not all have it at hand. Fortunately, something quite simple has been found to give good results. This consists of equal parts of the best loam procurable, sharp sand, and leaf-mould with a dash of old lime rubble and all in a finely divided state. I still recommend leaf-mould, despite the oft-reiterated warnings that this addition is anathema to carnations.

For the first potting use clean 2½in. diameter pots; lightly work in the mixture, taking especial care that the plant is not set too deeply in the pot. Place the plants on a shelf near the glass in a warm house, watering carefully until roots appear through the new compost. In from four to five weeks roots make their appearance, and preparations should be made for repotting as the plants are not favoured by being too long in the heated structure.

In this case, 3½in. diameter pots will be found a suitable size, affording just sufficient room for new soil to keep the roots moderately active for the winter months. Yet it is not enough to retain a superabundance of water and induce a water-logged condition of the soil. The soil mixture for use in this potting contains the same ingredients as last, with the proviso of more loam and less leaf-mould, with the materials in a rougher state after mixing. The necessity of good drainage is too obvious to be insisted on; while firm potting is essential, supporting each plant with a neat stake.

The situation is again a shelf near the glass, a temporary fixture in the carnation house, where the plants make a slow and sturdy growth; and as a preventive of ills, give a light dusting of 2 parts sulphur to 1 part lime.

Early in the New Year the plants will be from 6ins. to 8ins. high, when the points should be nipped clean out to induce the plants to "break." Pinching at this height will usually supply enough side growths to form a good plant and, apart from adventitious flowering shoots, little more pinching is necessary.

Repotting as required into larger pots and gradually acclimatising the plants to out-of-door conditions as the season advances, with only overhead protection, and staking when needed, are routine work.

It is important to remember that the judicious use or otherwise of the watering can, especially at this season, will determine the ultimate fate of the plants for good or ill. The fibrous root system developed under semi-dry conditions: the narrow, sharp-pointed, rather succulent leaves with a smooth, waxy surface, capable of restricting transpiration, all point to the necessity of careful watering in the cultivation of these desirable flowers.—WM. MCCARRELL.

BOUGAINVILLEA GLABRA, A MOST VALUABLE AND DECORATIVE GREENHOUSE CLIMBER.

Primroses in Pots.

ALTHOUGH one would not wish to lift primrose roots from beds or borders, where they have been planted to give a spring effect, it is a good plan to pot up any roots which can be spared. These, if lifted with care during November, can be relied upon to break into flower in mid-winter and give a welcome promise of brighter days to come. The roots selected should be as sturdy as possible and these require somewhat careful potting in a soil of good quality. Pay special attention to the matter of drainage as, although primroses like plenty of moisture, they are impatient of a water-logged soil. Of course the roots may be kept in a cold greenhouse, but much better results are secured if the plants can have a little warmth. A position in a declining hot bed stimulates a free growth and, in such conditions, flowers and foliage are freely produced. In growing these early primroses, free ventilation is important, as, when the atmosphere is stagnant, there is a great danger of the blooms damping off. This plan is well worth adopting with the ordinary primrose, but the coloured forms and the polyanthus varieties will be found to be just as amenable to the treatment.—S. L. BASTIN.

FLOWER GARDEN NOTES

Some Fritillarias.

THERE is something peculiarly fascinating in these quaint and decidedly pretty plants, and it is a matter for regret that representative collections are not more numerous; for the many and varied species are, for the most part, accommodating plants and capable of creating interesting and very beautiful effects in the rock garden and woodland. The Crown Imperial (F. Imperialis) and the indigenous F. Meleagris are two well known and well loved plants and should stimulate an interest in their congeners from California, eastern Europe and Asia, and one of the most lovely is F. pudica, a lovely plant but 6ins. to 9ins. high and bearing, usually, a solitary, but occasionally twin, bell of clear bright yellow, a plant of unusual interest and beauty and worthy of a conspicuous station in the rock garden.

F. recurva, from California, sometimes proves a little fastidious and prefers a hot and dry position in a sheltered spot; many will prefer to grow the easier F. coccinea, of the same bright red colouring as recurva and, indeed, a delightful plant.

F. pyrenaica, from the Pyrenees, has plum-coloured bells, reflexed, the inside of olive green, and it is, moreover, of the easiest cultivation in border or rockery, where, also, its quaint companion, F. ruthenica, with drooping bells of almost black, will be quite at home. Other quaint and somewhat sinister species are F. camchatcensis, with pyramidal spikes of purplish black flowers, from eastern Siberia; F. lanceolata, dull purple, from north-west America; F. glauca, with broad greenish white bells from California; and F. Thunbergii, with greenish and pale bells purple, from China and Japan.

F. pallidiflora is a noble plant, varying in height from 9ins. to 2ft., according to the conditions under which it grows; it enjoys a half-shaded situation, with a soil rich in humus, and in early spring its large yellow flowers, beautifully chequered inside, are a garden delight and should long ago have obtained for this plant greater popularity than it has hitherto enjoyed.

F. aurea, with black and yellow flowers, is a fine and pretty plant and is easily managed; a dwarf plant from Cilicia. Very quaint is the sombre F. acmopetala, from Asia Minor, with drooping bells of purple and green on stems rather more than a foot in height; it is a good plants for border or rockery.

There are many more species and varietal forms of these charming plants, and all who grow some of them crave for more, as the fascination and charm with which most bulbous plants are pregnant are especially strong in these unique, quaint and withal very beautiful subjects. For the rock garden, thin woodland or the border of choice bulbs and plants, they are ideal, and the greater part of them are exceedingly happy under pot culture, and, so grown, are interesting and lovely adornments of the cool glasshouse during the days of early spring.—RALPH E. ARNOLD.

THE FAVOURITE SNAKESHEAD FRITILLARY.

CROWN IMPERIALS SHOULD BE GROWN IN EVERY GARDEN.

A Hardy Cyclamen.

NESTLING in a little recess with boulders perpendicularly built up behind the bed to ward off biting winds, Cyclamen cilicicum is in good form, and shows buds enough to ensure continuation of bloom for several weeks to come. The whiteness of its petals is enhanced by the rich purple of the base of the flower, and the foliage, too, just gives the foundation over which the flowers show up to fine effect. Sometimes one hears complaints that the cyclamen are too difficult, but under fair treatment they will thrive and increase in effectiveness year by year. Too often the start is made with imported corms of uncertain age, collected and buffeted about until dried to the extreme, and when such corms are planted in soil which holds a deal of moisture, it is small wonder they fail.

Infinitely better would it be to start with a few pot roots which have been properly grown in a British nursery, and with such stock the only further need is to provide good drainage, some old lime rubble, a good turfy loam and a little fibrous peat. During the flowering period the soil may, with advantage, be covered with half an inch of coconut fibre, but when the last of the flowers has faded a couple of inches of loose, flakey oak-leaf mould may be spread over the entire bed, covering the corms as well as the soil.

When once a stock of cyclamen has been established it will be plain sailing to produce fresh stock, for one needs but to watch the ripening of the seed pods and sow seeds immediately they are thoroughly ripened to ensure success.

Crock pots to the half-way line, covering the crocks with the fibre of peat siftings.

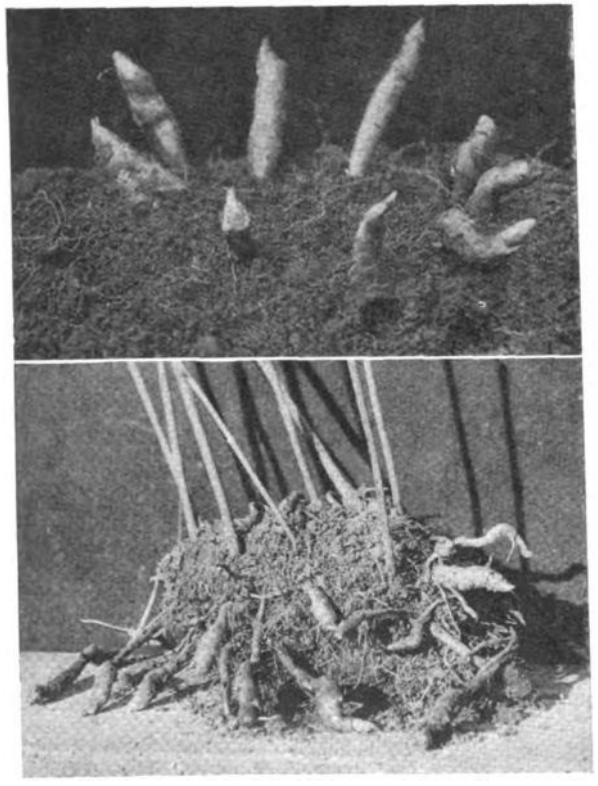
Digitized by Google

Use a compost of equal parts sifted loam and peat, with sharp sand and charcoal to keep it open. Scald the soil with boiling water after filling the pots, and sow the seeds next day, covering a little more than a quarter-inch with a similar compost. A cool house is best for germinating the seed, but a frame, kept close, will be satisfactory. When the seedlings make second leaves pot them off in thumb pots, using similar compost to that advised for seed sowing. Plant out when growing nicely and thenceforward leave the roots undisturbed.

Although generally recommended for rock work, the cyclamen are very suitable companions for wood anemones, around the roots of trees.

Keeping Perennial Sunflowers in Check.

THOSE who grow the perennial sunflowers know well their trespassing character and the great difficulty there is in keeping the plants within bounds of the space allotted to them.



A CLUMP OF TUBERS AS REMOVED FROM THE SOIL AND REPLANTED SEPARATELY AFTER DIVISION.

One may dig around the plants, for instance, and in doing so cut off one of the tubers; this may be unnoticed until a new plant is seen growing in a spot where it is least wanted—for every bit of tuber will grow into a new plant. Again, attempts may be made to divide the clump of roots, or even remove it from the ground entirely, but sure enough a little piece will be left behind to assert itself later on, or be carried or dropped upon another part of the garden, where it will soon establish a vigorous colony of rambling roots.

Such a plant needs a special system of culture. Left to itself for one season only, one clump of tubers would take possession of several square feet of ground, and in time the sunflowers would dominate the whole garden. A study of the illustration showing a clump removed from the ground will demonstrate its powers of increase, for each tuber, small and great, will form a root system of its own after travelling a considerable distance underground.

The best way to check its activities is to remove the clump from the ground each year as soon as flowering is over and the stems begin to wither; in doing so, every vestige of root and tuber must be taken out, and the soil deeply dug. Then all the largest tubers should be pulled from the mass of roots, and the remainder thrown upon the rubbish heap to be burnt.

The tubers should be replanted a few inches below the surface of the ground. The number used depends upon the size the new clump is to be. Each tuber will send up a stem, so it is easy to judge the eventual effect.

A neat group can be made by planting the tubers in a circle, with a stout stake in the centre to which the stems may be secured later on, and which will, therefore, grow up straight.

The result of this treatment is very tall stems and large flowers, so useful for cutting in the late autumn, because of selection of the best tubers each year; and there is no annoying trespassing upon the space occupied by other flowers in the border.—H. A. D.

The Variegated Monkshood.

SOME years ago it was decreed by those who govern nomenclature of plants by incessantly altering the names of old favourites that what we had long called AconitumNapellus bicolor should be called Aconitum variegatum. It is not a happily chosen name, because "variegatum" causes one instantly to think of variegated foliage. This plant has normal green foliage, but blue and white flowers, and bicolor is the recognised appellation for flowers which partake about equally of two distinct colours. The old name sticks to this plant, and is the best name. The fact that it reproduces itself true from seed may indicate that it is not a mere form or variety of Aconitum Napellus, but it could still be called A. bicolor.

Whatever its name, it is a really good plant, and the way to see it at its best is to divide and plant single crowns about a foot apart in groups of anything from half a dozen to a score of pieces. Provide a well nourished, porous soil, and give an annual summer mulch of some littery manure. Repeat the division before the plants become crowded.

A Yellow-flowered Peony.

YELLOW is not frequent in the peony tribe, but Pæonia Wittmanniana is a particularly pleasing flower with clear, clean-looking, sulphur yellow blossoms on plants of comparatively dwarf stature.

It is worthy of inclusion in the most select collections, and is also one that may well form a prominent feature of herbaceous borders even where no other peony is grown. It is essential, as with the rest of the tribe, to select a spot where the plants may be left undisturbed for a period of several years, for that is the secret of securing satisfactory results where a plant may not produce a good bloom until it has completed a couple of seasons' growth. With its handsome foliage which can be made to act as a protection to numerous half hardy subjects, and its decorative flowers it is a plant to grow.

CUT FLOWERS IN WINTER

CUT flowers are doubly welcome in the house during the dull days of winter, and as blossoms are somewhat scarce at this season it pays to take care of those one does secure. Here are a few hints, all of which have been proved to be very useful in making cut blooms retain their freshness for as long as possible.

Up to Christmas, chrysanthemums are largely used, and one very important point is to see that the stalks actually under water are stripped of foliage. If the leaves are allowed to remain they will have a souring effect on the water, which will make the flowers fade quickly. With chrysanthemums, and all flowers with somewhat woody stalks, it is a good plan to pare away the rind for an inch or so at the bottom of the stem. Flowers with more or less succulent stems, as is the case with so many of the forced bulb blooms, should always have their stalks cut on the slant. When the stalks are cut straight across, as is usually done, this part rests closely on the bottom of the vase, and it is most difficult for the flower to draw up enough moisture to keep it going.

How to Treat Flowers on Arrival.

It is a very great mistake to arrange flowers in vases straight away. They will last much longer if, before being introduced into a warm room, they are placed in jars of water which are stood in a cool place. Many people recommend that the water in the vases should be changed each day, and this is really a good plan. The flowers seem to benefit by the re-arrangement, for then any faded ones can be removed. It is always a bad thing to leave a fading flower in a vase, as this will quickly have an effect on the others. Undoubtedly, the addition of certain substances to the water in which the flowers are placed helps the absorption of moisture. Even a pinch of salt is better than nothing, and flowers are found to last a surprisingly long time if a tiny lump of camphor is put into each vase.

Cut flowers in a room should never be allowed to stand in direct sunshine. This will cause them to wilt more quickly than anything else. Blossoms also fade quickly when kept on mantelshelves or in positions near to the fireplace. If it is desired to have vases of flowers in these situations, do not leave them there for more than a few hours at a time, afterwards giving them spells in other parts of the room. At the end of the day it is an excellent plan to remove all the vases from the rooms and group them in a cool place, such as on a scullery floor.

Reviving Wilted Blooms.

When flowers are abundant in the summer one hardly troubles about reviving those that are wilted. In the winter blossoms are so precious that they should never be thrown away until it is quite certain that there is no hope of their picking up. The hot-water treatment will usually give surprising results in the case of flowers that show signs of fading. Into a bowl pour scalding hot water to the depth of about an inch. Cut a tiny section from the ends of the stalks, and then put into the hot water. Remove the bowl to a cool, dark place and leave for a few hours. The blossoms will now seem to have taken on a new lease of life, and in many cases they will be almost as good as when they were fresh. The part of the stalk that was actually in the water will be pulpy, and this should be cut away before the blossoms are put into the vases once more.

LEONARD BASTIN.

GARDENING WITHOUT A GARDENER

Phloxes and Pyrethrums for Every Garden.

THESE handsome perennials thrive well in almost any soil, provided the site is deeply dug and well manured previous to planting. They are both excellent plants for a herbaceous border and are capable of giving a wealth of bloom. The gaily coloured daisy-like flowers of the pyrethrum are produced during early summer; the early varieties of herbaceous phloxes come into flower in July, and the late varieties continue until September. The following is a short list of some of the brightest and best:

PHLOXES.

ANTONIN MERCIE.—*Mauve with a creamy white eye.*
BARON VON DEDEM.—*Brilliant orange scarlet.*
DEUTSCHLAND.—*Large truss of vivid orange red.*
ELIZABETH CAMPBELL.—*Soft salmon pink with a white centre.*
FRAU ANT. BUCHNER.—*Pure white, large truss.*
JOSEPHINE GERBEAUX.—*Cherry red, edged white.*
LA NEIGE.—*Pure white.*
LE MAHDI.—*Dark purple violet.*
MRS. M. VAN HOBOKEN.—*Soft self pink.*
MRS. RUTGERS.—*Light rosy lilac with lighter eye; enormous truss.*
WILLIAM RAMSEY.—*Deep glowing purple, late flowering.*

PYRETHRUMS.

BEATRICE KELWAY.—*Cherry rose, single.*
HAMLET.—*Soft pink, single.*
J. N. TWERDY.—*Crimson tipped golden yellow, double.*
LA NEIGE.—*White with a pale mauve centre, double.*
LANGPORT SCARLET.—*Brilliant scarlet, single.*
QUEEN MARY.—*Clear pink, double, fine for cutting.*

A Decorative St. John's Wort.

AMONG the dwarf hypericums suitable for the rock garden and retaining walls, H. polyphyllum is certainly the best and the most reliable. It has much the same habit as H. olympicum, but is smaller and more compact in growth. The glaucous opposite leaves are on semi-prostrate stems 5ins. to 8ins. in length, and the bright golden yellow flowers are about the size of a half-crown. These are produced in clusters of two or three at the end of the shoots, and the prominent golden stamens are not the least attractive part of the blossoms. A specimen with fifty or more flowers opening at the same time in June is a remarkable and wonderful sight, for this delightful St. John's wort is very floriferous.

The subject of this note is not particular in regard to position, providing it is given a light and sunny spot. A crevice or fissure would be excellent, or a chink where the graceful shoots could spread over a rock or stone, while in a wall it would be seen to advantage. It will thrive in any well drained soil, and a heavy rooting medium can be improved by adding old mortar rubble, grit or stone chippings. Young growths made into cuttings will readily form roots during August and September if placed in sandy soil and set in a cold frame. In two years they make nice flowering specimens. —T. W. B.

The Common Rest-Harrow.

A WELL known seaside plant in many places is Ononis fruticosa, and some few people may be found who grow it in their gardens. But, wherever it has been tried, the allied but very distinct O. rotundifolia, the round-leaved rest-harrow, is greatly appreciated for its beauty and distinctness. It has to be admitted, however, that it is not quite so hardy as we should like, and that, in severe winters, it may be killed. Happily, it is easily raised from seeds, and self-sown seedlings often spring up near the old plants and stand the winter much better than they. O. fruticosa loves a dry soil and a sunny position. It grows from 12ins. to 18ins. high and has very pretty rounded leaves and rose pink vetch-like flowers. This ononis is truly a charming though not a showy plant, deserving to be considered fully in adding more hardy flowers to the rock garden. It may be easily raised from seeds or propagated by cuttings.

Daphne Mezereum.

A valuable early-flowering shrub for small gardens.

ALL flowers that reveal their beauty at the beginning of the year are welcome, but none more so than those which bring in their train perfume. Among dwarf hardy flowering shrubs which belong to this precious order, the daphnes are not the least valued. The most popular is D. Mezereum, which seldom exceeds more than 3ft. in height, its closely studded buds on erect shoots, broadening into rich purple, before the end of January in mild winters. The blossoms precede the time of the opening of leaves, and I think the fragrance of this old favourite accounts for it being found in many gardens. It does well in town and suburban gardens too, and it is well understood that, if only the sprays of buds are taken into the warmth of a room and placed in water, they, like the winter jasmine, soon open. The culture of this daphne is not at all difficult, otherwise we should not find it growing in so many different localities throughout the country. To ensure its success, however, it ought to be given the advantage of a rich, deep and, above all, a well drained soil, and an open situation, away from overhanging trees. During the heat of summer, when other things in flower claim our time, daphnes are liable to suffer from dryness at the roots; but those who can picture in their mind's eye a garden in winter, with its bareness, will see to Daphne Mezereum does not lack fo as to endanger its chance of bringing bri in January, when one may expect to loo flowers appearing, and be full of co the weeks which succeed. It need or no pruning of any account.

Dahlias and Tulips in Alter Displays.

NOW that the frost has brought the fl of the dahlias to a sudden e another season, there should be as litt as possible in lifting the tubers an drying, storing them in a dry, fro place. If this job is left over inde apart from the risk of a sudden seve damaging the tubers themselves, if t left in the ground much later, the s tend to become more sodden as days thus making the lifting and drying difficult and messy business than if i in hand at once.

The soil in which my dahlias are g

A BOLD CLUMP OF THE DWARF WHITE PHLOX LA NEIGE.

a heavy loam, which is decidedly un to work after a few days rain. I hav that by using plenty of lime at the planting—both when the dahlia is pla afterwards, spread round the colla plant—the tubers come up very muc and drier than otherwise would be t Incidentally the lime checks the depr of slugs.

One large formal bed surrounded paving was filled with dahlias of the n peony type; most of the varieties of are particularly decorative in growth suitable for the purpose indicated. N the dahlias are removed the ground dug over, rotten manure, lime a ashes incorporated therewith, and th bed prepared for planting with Darwi In this particular bed, dahlias and tul alternated in this way for the last fe and the results have been particular fying. The soil has plenty of heart addition of manure and ashes, with the lime, above mentioned, is in maintaining good displays of each —H. H. C.

Hints on the Treatment

e Onion Bed.

cultivator who has to deal with a light, andy soil, can grow early, small and pened bulbs, but he cannot compete, rds size, with the one who possesses y or clayey loam. The sandy soil does tain nutriment long and beyond being ed now, should not be treated, before March, for the year's crop. In such he best way to feed is to apply surface gs and surface feeding with liquid e from June to the end of August. case of heavy soils some extra work is ry in preparing them for next year's Although such are the best soils, as above, they must be attended to in ime and made ready for the reception of or plants in spring. The plants are mainly raised in boxes under glass and transplanted in April. It is unwise to he soil while it is in a wet, sticky state. it can be manipulated without much hering to the tools, get the ground ed quite 3ft. deep, break up the sub- ut leave it below, and from bottom to x manure with the soil; also a liberal g of wood ashes and burnt soil. The rming the top 1ft. layer should be left ough state, that is, the lumps should broken; avoid a close surface as we he air, frosts and rains to penetrate Ground treated in this way may not neat appearance, but in the spring umps will crumble to powder, especially e lime has been scattered on it prior ristmas. The cultivator will find it sure to prepare the surface for young or for seeds. The time to deal with face soil is when drying winds prevail, on a day following a night frost or the ll retain its pasty condition for a long G. G.

Root or Finger-and-Toe."

a fact that the troublesome fungoid ease known as club root or finger- e, is often introduced into the garden ots of wallflowers, cabbage plants, etc., rchased. This trouble never affects t cruciferous plants, such as the turnip, e, wallflowers and certain common like charlock and shepherd's purse. pores, which can remain dormant in l for many years, are carried about by d roots or soil. Just one affected ft in the soil, is quite capable of spread- e disease throughout a whole plot.

A CL ur gardeners who buy their cabbages allflowers in small lots, should always any specimen which, by the malformed shows signs of having the disease. the If the plants appear to be healthy, it is to t wise plan to treat them in the following Our. Mix in a pail a handful each of and lime, soot and soil, finally adding this nt water to make a creamy paste. Stir seeots of the plants round in this and even wan them in it for a little while before setting into the soil.

mad from which infected plants have been remed ought not to grow any cruciferous sure for three or four years at least. Keep to a sharp look out for weeds, especially drop a cruciferous nature. These should whe be pulled up and burned and not of r left to rot away. As a matter of Sue risk of infection is greatly increased cultowing the roots to decay as, when one dry, the spores of the fungus are spread of ser the place. It is a very harmful the ure to allow cabbage plants to remain gard in the ground, as even a few decaying a ck may infect wide areas of soil.

dem fungus which causes the trouble is tubest in an acid soil and, on this account, fresh organic manure and certain acid artificials should not be used where club root is feared. Lime may be freely employed, for this is one of the best antidotes to acidity and therefore is likely to prevent the spread of finger-and-toe trouble. It is a good plan to dress soil with gas lime immediately after removing the crop. When the pest is known to be present the ground infested should be dressed at the rate of about 3lb. of quicklime to each square yard. Soils naturally rich in lime are almost invariably free from the fungus that causes club root.—S. LEONARD BASTIN.

Forcing Rhubarb Out of Doors.

AN easy and most convenient method of forcing rhubarb in the permanent beds is here illustrated. Some stout stakes—bean poles, or wood cut from the hedge or lopped from trees—are inserted in the ground around the rhubarb root or roots, forming

AN ECOMONICAL METHOD OF FORCING RHUBARB.

a circle. Around this palisade is then massed rotted manure and leaves, and over this any leafy material from the garden—grass cuttings, weed refuse, etc. The rhubarb is thus enclosed in a hot-bed, which may be piled up as high as the stakes will accommodate it, and the shoots soon respond to the warmth. As the weather gets very cold a mat or other protection may be thrown over the top of the stakes, especially when heavy rainfall or snow occurs.

Early rhubarb may also be obtained without the use of manure, which is, nowadays, a precious material. A mixture of leaves, grass and other light vegetable refuse could be similarly piled up against the stakes, which, if it does not generate heat, will form a very warm protection and induce an early crop of welcome "sticks."—H. A. D.

Protecting Late Cauliflowers.

PROBABLY the actual foliage of a cauliflower is not more likely to be damaged by frost than that of any other of the cabbage tribe. When sharp weather comes it is the white "flower" that suffers, and this may be so affected that it turns brown and finally rots away. Towards the end of November, at the latest, the grower should certainly take steps to protect any cauliflower that may still remain. The old-fashioned plan of breaking a few of the leaves a little so that these cluster over the centre of the plant fails to an extent because it does not prevent the moisture reaching the curd, as the white part is properly called. The curd always suffers much more from frost if it happens to be wet when the temperature falls below freezing point. A far better way is to gather the outer leaves of the plant together and then tie securely towards the top so that a regular canopy is formed over the heart of the cauliflower. This tying up should always be done when the curd is dry. Of course, where it is wished to clear the ground on which the cauliflowers have completed their growth, they may be lifted. Get them right up with a fork by the roots and then hang head downwards in any dark cool place. Here they will remain in good condition for quite a long while, though they should be used as soon as the leaves show signs of turning yellow.—L. B.

Winter Pruning the Bush Apple.

WINTER pruning may commence at any time after the leaves have fallen in autumn, but it is best to avoid pruning in the dead of winter, and if it has been found impossible to prune in late autumn or early winter it is best left until the middle of winter is passed.

The object of pruning a bearing tree is to help it to produce a good set of fruit in the immediate season and induce the formation of an ample number of fruit buds for the following season's crop.

First remove dead branches and branches which are rubbing or crossing. It is also desirable to remove branches which are diseased, *e.g.*, cankered, provided that the amount of cutting required is not excessive. Where a lot of cutting is necessary it is best to perform this operation in several years, removing one branch each year and training in new growths to fill in the space.

The branches should be sawn off as near the main limb as possible and the cut smoothed over with a sharp knife close to the limb and the wound dressed with some preparation such as Stockholm tar. This enables the wound to heal quickly and prevents the entry of fungus spores.

The next step is the removal of shoots or branches whose presence is undesirable owing to their position, to admit light and air to the centre of the bush.

For the purposes of pruning we may recognise three types of growth:

(1) *Leaders.*—One year old wood which forms the leading shoots of the main branches of the bush.

(2) *Laterals.*—One year old wood springing from axillary buds on spurs or branches.

(3) *Spurs.*—Condensed shoots of varying age upon which most of the fruit is borne.

The ideal bush is one that has all its branches well furnished with spurs, yet is vigorous enough to produce shoots for further growth.

The greater the vigour of the tree the less severe the cutting, as hard pruning vigorous shoots tends to produce the development of fresh shoot growth.

Leaders of the more vigorous-growing varieties, such as Bramley's Seedling, Newtown Wonder, etc., should have a few inches at the tip removed; moderate growers, as Cox's Orange Pippin, Worcester Pearmain, etc., should be reduced one-third; while weak growers, such as Lane's Prince Albert, may be shortened one-half. Always cut the leaders to an outside bud, unless the natural habit of the variety is spreading, *e.g.*, Lane's, when the cut should be made to a bud pointing inward. The cut should

Digitized by Google

be a sloping one, commencing from the side opposite the bud and about a quarter of an inch above it, cutting upwards. Lateral growths of less than 5ins. should remain unpruned, and in some cases—*e.g.*, Worcester Pearmain, where fruit is often borne at the ends of slightly longer shoots—they may be left longer, but should be cut back the year following. Fruit buds can be distinguished from wood buds, as they are much plumper and more oval, wood buds being narrow and pointed. Cut back the laterals of the more vigorous sorts to about five good buds, and of the weaker sorts to two or three buds.—H. B.

Black Currant Mite.

THE attack of this serious pest on black currant bushes is characterised by the abnormal size and roundness of the buds on the twigs, in consequence of which the disease is often referred to as "Big Bud." Swollen buds may be present in large numbers, or they may be few and accompanied on the same twig by normal sized, healthy ones, but in all cases, where such enlarged buds are present at all, practically the same danger exists.

Apart from their size, these enlarged buds show no external signs of being unhealthy or diseased, and even if cut open in winter they do not, as a rule, differ very markedly in their interior from healthy buds, except, perhaps, for a certain paleness of colour when examined by the naked eye. As spring approaches, however, the central portions of these buds become withered, brown and dead-looking, and a process of drying-up takes place, beginning at the centre of the bud and proceeding outwards. These buds do not unfold in the spring, or if a few of them happen to do so, they only produce feeble and sickly shoots, with no fruit; in most cases they persist for some time and remain as dried-up and dead structures on the older wood.

A very large number of whitish grub-like creatures are to be found inside the swollen buds, which are too small to be seen with the naked eye; these are known as gall-mites. The presence and activities of these mites at first stimulates the buds to increased growth, so that they become enlarged above the normal size, also destroying the structures within the bud. The mites produce eggs inside, so that rapid multiplication of their numbers takes place within the buds.

Chiefly in April and May the mites migrate from the swollen buds and, crawling over twigs, enter the new buds which are being formed in the axils of the newly-produced leaves. Here they live and multiply and hence cause a further production of swollen buds, consequently, in a season or two, practically the whole of the buds on a bush may become affected and the bush rendered useless.

This pest has most probably been spread over the country by the distribution and planting of cuttings from affected bushes on which swollen buds were present. The very greatest care should, therefore, be taken when obtaining fresh stocks of black currants to see that the new plants are absolutely free from this pest, and even go to the trouble of having a guarantee.

Spraying and dusting affected bushes fail to give results of any practical value. Seeing that for the greater part of their lifetime the mites are safely housed within the interior of affected buds, and can only be destroyed by them while in the act of migration from bud to bud.

When the attack is but slight its progress may be delayed by carefully cutting off and burning during the winter every single twig which bears a swollen bud, but in practically all cases the best method of procedure is to grub up and burn every affected bush in its entirety.—H. S. PATTON.

WHAT OUR READERS SAY

FLOWERS FOR A WOODLAND GARDEN.

SIR,—Your correspondent who has taken in part of a copse into his garden has a delightful opportunity, but let me warn him to be very careful in introducing Symphoricarpus racemosus, as suggested on page 657 of THE GARDEN for November 13th. In fact, it is better left out of the scheme. I, unfortunately, suffer from a hedge of it, not on my own property. It wanders in for many yards and is impossible to exterminate, tough underground stems sending up suckers everywhere. It has absolutely ruined a small rock garden in its vicinity. Its flower is quite inconspicuous, and its berries too scattered to produce any sort of effect.—M. R., *Cambridge.*

HEUCHERA TIARELLOIDES.

SIR,—Some fine varieties of Heuchera were noted in a recent issue of THE GARDEN, and these are now well known to most garden lovers. The most brilliant include sanguinea, Pluie de Feu and Fusee; but with us, on a light sandy soil, they make very poor growth in a dry summer, such as the recent one. Planted on a well manured north border, shaded by a hedge, they do much better. One variety worthy of special attention is Heuchera tiarelloides, which is a cross between a hybrid heuchera and Tiarella cordifolia, introduced by Lemoine. It is a most vigorous grower, making a compact plant with foliage of a pale green, and brown markings, and retains its freshness throughout the winter. The blooming period commences in May and lasts several weeks, during which time the plant gives an abundance of spikes of pale flesh-coloured flowerets, developing to a deep pink, thus producing an extremely pretty effect. There is also a pure white form of it which should be included in any collection.—F. L., *Bournemouth.*

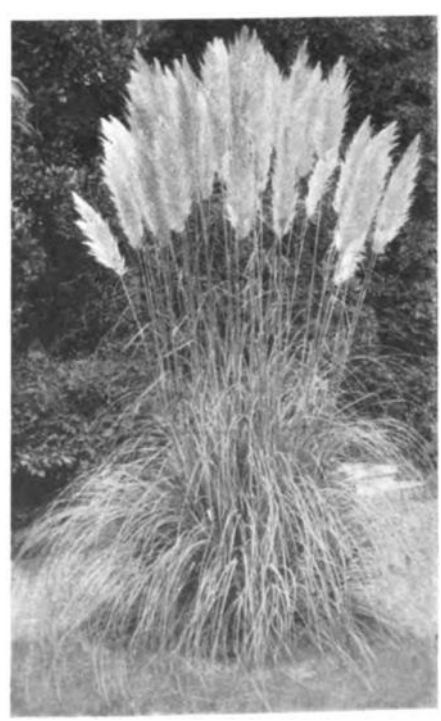
PROPAGATION OF THE WITCH HAZEL.

SIR,—It appears fairly obvious that the plant referred to by your correspondent, "W. J. B.," on page 605, is Bryophyllum pinnatum, a plant of easy culture in any good garden soil. "E. C.," on page 596, says of Hamamelis that, unfortunately, they are rather difficult to propagate, but I have always found it very easy to graft them on seedlings of H. virginiana under glass early in the year and bushy plants 2ft. high are procured by the end of September.—WM. H. JUDD, *Arnold Arboretum.*

PAMPAS GRASS FOR GARDEN DECORATION.

SIR,—I thought the accompanying illustration of a clump of pampas grass might interest many readers of THE GARDEN, and encourage them to grow it as a decorative plant.

A friend of mine gave me the clump of pampas grass two years ago, and it has made the wonderful growth shown in the illustration. It is over 9ft. high and has forty spikes. It has been admired by many visitors to the garden.—S. E. TATTERSHALL, *Orpington.*



A CLUMP OF PAMPAS GRASS MAKES AN ADMIRABLE GARDEN DECORATION.

DUAL PURPOSE APPLES.

SIR,—I notice that in my list of dual purpose apples THE GARDEN for November 6th, I omitted one apple which I should have placed first on the list and that is The Queen. This variety is a most consistent and heavy cropper with me and is really one of those apples which, when one is making out a short list, should be classed as indispensable.

Although classed in many catalogues as a cooker, I have found it being sold (and for a good price), as a dessert variety. Its season overlaps that of Worcester Pearmain. The flavour is rather acid, but it is quite good for dessert—especially on a hot day when a sharp apple is very welcome.

Rather large and flat, the skin is yellow with red stripes almost covering the sunny side of the fruit. Growth is inclined to be spreading and care is needed when pruning to preserve a good shape. The only fault of the variety seems to be a great susceptibility to apple scab, which I am combating with Bordeaux mixture.—N. D. H.

CHRYSOBACTRON OR BULBINELLA HOOKERII.

SIR,—Still more largely grown as chrysobactron, rather than under its authoritative name of Bulbinella Hookerii, this pleasing plant remains none too plentiful, although introduced from New Zealand as far back as 1850. It is rather difficult to account for its comparative scarcity, though it is by no means a rare plant. I am of opinion that want of moisture at the roots is sometimes accountable for its demise, as there appears no other reason, seeing that it is admittedly hardy in all parts of the United Kingdom. In dry, sandy soils it frequently dies out, while in those which are of rather moist character it appears to flourish and be a long-liver. Its height is generally about a foot in our gardens, but it is said to be sometimes up to 3½ft. in stature. It has long, narrow leaves and spikes of yellow flowers. These are very

Digitized by Google

bright and effective, especially when there are several plants in a group. There are two forms of B. Hookerii in existence, although the taller and finer one with blooms with broader segments appears to be really rare. I first came across this form in the garden of a now departed keen gardener in Falkirk, where it was grown beside the smaller form and showed its undoubted superiority, but I have not seen this variety for a very long time. B. Hookerii may be raised from seeds or increased by careful division of established plants. By the way, has B. Rossii never yet come into cultivation in this country? It is said to be much finer.—S. ARNOTT.

HINTS ON PACKING PLANTS.

SIR,—As a postscript to Mr. Clarence Elliott's note on the packing of plants collected abroad on page 653 of THE GARDEN, I suggest that after washing the roots and wrapping *these* in *just* damp moss (or damp paper), wrap up well in waxed paper (such as confectioners use), and post them in envelopes as *letters*. Sent thus they arrive in excellent condition for Mr. Elliott's sand and leaf soil further method.—C. M. B., *Whitwell*.

ASTER ELEGANS.

SIR,—The accompanying illustration of a border of asters growing in my garden may be of interest to a few of your readers. The aster is the single variety elegans, with rich dark foliage and large flowers fully 3ins. or 4ins. across. It looks most effective and is, moreover, an easily grown plant and worthy of more extensive cultivation.—M. S., *Ecclesall, Sheffield*.

AN EFFECTIVE BORDER OF ASTER ELEGANS.

ROSE MERMAID.

SIR,—"A. J. M." attributes many virtues to the beautiful Rose Mermaid, and he does not exaggerate; but he has omitted to mention what, to my mind, is its greatest value. Whereas most roses must have sun, Mermaid will grow and flourish with a northern aspect. I have a plant on a wall facing north and the lack of sun seems to increase the wonderful "varnish" of the foliage, which, with this aspect, is mainly a reddish bronze. It blooms late in the summer, over a period of many weeks. If "A. J. M." will float a few of the shining leaves, with two or three flowers (cut before the bees have visited and spoilt the glory of the golden anthers), in a wide black or deep blue bowl, he will agree there is little left to be desired from a point of beauty. Can anyone inform us as to the parentage of this rose and to whom we are indebted for it?—GWENDOLYN ANLEY, *Woking*.

POPPIES IN NOVEMBER.

SIR,—As a regular reader of THE GARDEN I think the following will be interesting. Can any of your readers beat it? To-day, November 11th (Remembrance Day), a perfect bloom of a Soldier Poppy, Papaver orientale, was picked in a garden in Truro.—ARTHUR P. NORTH.

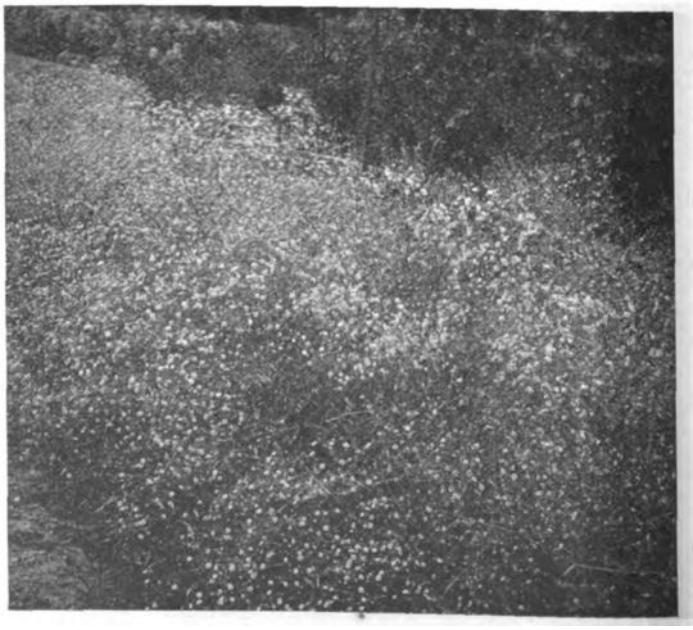
NURSERIES OF THE BRITISH ISLES.—VIII

THE HARDY PLANT NURSERIES, MERSTHAM.

AMONG our more youthful British nurseries which have secured for themselves an honoured place in the horticultural world, the Hardy Plant Nurseries at Merstham, Surrey, the business of Mr. W. Wells, junior, is one of the most outstanding examples. Since 1919 the progress has been rapid, until now it has become one of our leading nurseries devoted to the raising and growing of hardy plants. Reared in a horticultural family of considerable repute, Mr. Wells, junior, decided to break away from the old-fashioned methods and devote himself to the growing of plants which he thought would become popular. He has been correct in his surmise, and there is little doubt that his perseverance, energy and hard work during the last fifteen years have done much to popularise various types of our hardy flowers. Every year sees an addition to the grounds at Merstham, situated on the main road to Brighton and now the present area is close on 20 acres. As additions are made the virgin ground is hand trenched—an expensive operation, but one in which Mr. Wells thoroughly believes and which certainly seems to justify the extra labour if one has regard to the high quality of the material produced. On the occasion of our visit another five acres were being hand trenched and will be ready to be planted up in spring.

One point which will strike the visitor to these nurseries is the excellent arrangement and the general neatness and tidiness of the grounds. The plants are all robust, clean and healthy. There is almost an entire absence of weeds, so much so that some parts of the grounds have every appearance of a private garden. On the whole, there is a decided air of efficiency and well-being, which are not only reflected by the condition and quality of the plants growing in the nursery, but also by the staff themselves. Although only really established some thirteen years ago, the record of the firm is already famous. They have taken a foremost place in the production of many new varieties of various types of hardy plants, all of which are of considerable merit as garden plants. Mr. Wells himself would seem to have a *flair* for "spotting" plants that will appeal to the amateur gardener, after which he sets to work to develop and improve them, and finally to make them popular, not only in the gardens at home but also overseas. The popularity of Gentiana Farreri was, in the first instance, due to the keen interest taken in the plant by Mr. Wells, who raised large stocks of it. At Merstham the gentians do particularly well, and one can see rows of beds of GG. sino-ornata, Farreri, septemfida, Lagodechiana, acaulis, verna and other less well known species, such as pyrenaica. The plants are all in the best of health, fat and robust-looking, and certainly give a good account of themselves when flowering. To ensure the health and vigour of the stock plants on which he works Mr. Wells collects nearly all the European species himself when he is on holiday abroad. No special care is taken with the plants. Some grow in a sheltered border, others out in the open. Some grow in fat loamy soil; others, again, in medium soil with only a trace of lime, as Mr. Wells is not an ardent believer in lime for any of the species.

Delphiniums are also widely grown at the Nurseries, and during the last few years Mr. Wells has added a number of varieties



A BORDER OF THE FEATHERY GYPSOPHILA BRISTOL FAIRY.

Digitized by Google

to the list which have already become popular. At the height of the season somewhere about 100,000 plants are to be seen flowering in the Nurseries. Among the novelties raised at Merstham are the following: Mary Wells, of an electric blue colour; Mrs. W. Wells, with rosy mauve flowers rather loosely carried; Joan, a rich deep blue, which received an award of merit from the R.H.S., and Mrs. H. Kaye, award of merit, R.H.S.

Although Mr. Wells has achieved success in the growing and raising of delphiniums, it is with another race of hardy flowers, the perennial asters or Michaelmas daisies, that he has established his reputation as a specialist grower of hardy plants. On the occasion of our visit, the beds were a haze of colour—all shades of blue, through purples and mauves to deep pink. The planting of the beds has been done most skilfully, so that the visitor will see at a glance the characteristics, colour and habit of one variety standing out boldly, and not just appearing here and there in ill-defined groups. A selection can be made much more easily from such an arrangement than if all the varieties were grown alongside one another. It is impossible to detail anything like a representative list of the varieties to be seen. All the sections are represented, some by a few sorts, others by many; and the one variety which stood out head and shoulders above its neighbours was Aster Queen Mary, a real find. It is agreed by experts that it is the best of the Novi-Belgii yet raised, which, in other words, means it is one of the finest of our garden Michaelmas daisies. The flowers are large and shapely, some 2½ins. across, carried in rather attractive loose pyramidal clusters, and are of a delicate lavender blue shade which seems to blend with it a trace of pink, brought out in the sunlight. It is a first-rate flower, as the accompanying illustration of a bed of it will show, and, moreover, it lasts for a long time in bloom, fully three weeks. The extraordinary range in Michaelmas daisies can be well seen at Merstham. Varieties can now be had to suit almost any position in the garden border. There are dwarfs like Little Boy Blue for the front, medium sorts for the middle, and giants like Climax and Queen Mary for the rear rank. It is a hardy plant for the amateur gardener if there is one.

This year, by the introduction of a new double gypsophila known as Bristol Fairy, Mr. Wells has presented British gardens with a plant for which we have long been seeking. It is one of the most notable breaks we have seen for some years, and it bids fair to become one of the leading hardy plants of the future, not only as an inmate of gardens, but also as a first-rate market plant for interior decoration. This variety has all the elegance and appearance of the old double white variety, although its flowers are at least three times the size. It reaches a height of some 4–5ft. when growing outdoors, and it is perfectly hardy. It can be had in flower for about nine months in the year, and the flowers, on the whole, do not go off into that dingy yellow, but remain a pure white—unless, of course, the plant happens to grow in a soot-laden atmosphere. All the stock is being raised at Merstham, and Mr. Wells is so interested in the plant that he carries out the propagation of it himself. It is hoped that if a sufficient stock is raised, plants will be ready for distribution by next spring.

Any number of other hardy plants are grown, as well as a considerable number of alpines, including many of the Chinese and European primulas, which seem to do particularly well. The amateur will find many points of interest in the nursery, one being the method of plunging in beds adopted by Mr. Wells—principally for easy removal of the plants, but most certainly one which the plants like, judging by their health and vigour.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful and interesting hint sent in by a reader. Five shillings will be paid for all others published. Each must be sent in on a separate sheet and must not be more than 300 words in length.

THE HALF GUINEA HINT.

Strong and Lasting Pergola Posts.

The work of making a rustic fence or a pergola is generally carried out about this time of year, and a simple but effective way of building either of those structures is given here. Take out holes about a yard deep, place flags at the bottom, and on these stand large drain-pipes, collar down. Cement around the drain-pipe and just over the collar. When the cement is set put back the soil into the holes around the pipe. Then get your posts, place them in the drain-pipes, and fill up each pipe to the top with cement. The rims of the pipes should stand 6ins. above ground level. These posts will form an excellent foundation for the fence or pergola, and in a day or two, when the cement is quite firm, the crosspieces can be attached. I built one of these lines nine years ago, 23yds. long, 9ft. high, and not a nail put in since, and it has to hold a tremendous weight. —W. M.

Brightening a Dull Place.

My back-yard was the usual *cul de sac* from the back-door to the end of the outbuildings, paved because its aspect forbade all hope of growing anything there. My wife's remark as she placed out her house plants one day gave me an idea, which eventually developed into a definite scheme, the result of which exceeded my most sanguine expectations.

A number of boxes were made, mostly from grocers' empties, their size approximately 12ins. square by 9ins. deep. Some feet, 1in. thick, were fixed on the bottoms, holes were bored in the bottoms for drainage, and the outsides were painted.

A variety of hardy shrubs, such as box, retinosporas, privet, euonymus, green and variegated, were obtained and potted up in 8in. or 9in. pots. These were then plunged in the garden to become established. When established they were taken, as needed, and put in the boxes, a layer of mixed crocks and ashes, 1in. deep, being put in the bottom of each box first. With the pots in position, the surrounding space was filled up with fine ashes lightly rammed and made firm.

With a duplicate set of established potted plants on hand, it became a simple matter to brighten up the back-yard, the plants being changed at intervals of a week or so, those having done duty on the yard being returned to the garden to recuperate.

Flowering plants were used occasionally, but were of no further use after blooming; their use, however, was pleasing, and gave the evergreens a longer period in their garden quarters.—G. W. S.

Kniphofias: Preventing Crowns Decaying.

One of the surprises to those growing kniphofias—for the first time possibly—is that, although reputed to be quite hardy, they sometimes die off by spring. This is not altogether the experience of the tyro, either, for even with "old hands" failure occurs now and again. Not infrequently the cause is decay of crowns in consequence of the plants being left to themselves, and snow and wet reaching the centres they rot off. A remedy, which is very simple, is to place three stout stakes to each plant, tying up some of the long leaves to each. This is better than placing only one stake to a plant, and "bunching" the foliage to it, as the former method carries off the water to the outside of the clump.

Only stout stakes should be used, and thin sticks or canes left out of the arrangement, as they become loose through having no "purchase." In the spring, the old, worn-out foliage can be cut away and the stakes removed, there being no longer any need for the screen.—C.

A Cheap Insecticide.

A cheap insecticide for practically all sorts of blight and grub in the garden can be made from permanganate of potash. A quarter-pound of the crystals dissolved in boiling water will make a few gallons of solution. This solution can be kept in bottles, and when required for use must be diluted with cold water until it becomes the colour of red wine. I have found this a good insecticide for freeing loganberries from the grub frequently found in the fruit. Apply by lightly dressing the ground with the crystals in the vicinity of the plant in early autumn, or by watering the ground with the diluted solution in the autumn and again in February or March. It is also exceptionally good for spraying roses for grub and rust; also for keeping the celery fly from attacking celery.—I. F. F.

Moving Trees and Shrubs.

When it is desired to transfer certain trees and shrubs to another part of the garden, a difficulty is sometimes experienced in carrying out the removal single-handed without displacing more of the soil from the roots than is desirable. Small trees and shrubs often have a considerable amount of soil adhering to the mass of roots with which they are furnished, and their future success largely depends on the care exercised when dealing with them in the circumstances referred to. A plan that may be adopted with complete success is to work a shovel underneath the roots, after lifting them, and, if properly balanced, the whole ball may safely be drawn along the ground the required distance, by means of the handle. The weight will prevent the shovel slipping from underneath.—J. C.

WEEDS ON LAWNS: THEIR ERADICATION

BEFORE commencing the removal of weeds from a lawn, the thoughtful custodian will, with great advantage to the success of the work to be carried out, consider the following: (1) the cause of the weeds being present in the grass sward, (2) their prevention from again establishing themselves after removal, both in an established lawn or a prospective new one, and (3) how best to eradicate the weed pests now established and, most important of all, ensure that their places be taken by suitable grass plants, which alone make the perfect lawn. So we may consider weeds from the following angles of view, *i.e.*, cause, prevention and eradication.

Causes.

The cause of their presence can be traced to many reasons and, in the case of an established or new lawn, every *constant* effort ought to be employed in preventive work. Thus, it is essential to use only grass seed free from weed seeds, and when sowing, err on the side of a heavier amount than a lesser, because any bare place on a lawn will, unless grass seed is utilised, produce weed plants either from weed seeds, which are in all soils, or by forming a seed bed for wind-blown pests to establish themselves. Also, scythe or root out weed pests growing near a lawn before they seed. A frequent reason for weeds appearing is the application of compost dressings—now, such preparations generally contain a large proportion of soil and on test or examination, will be found infested with weed seeds, which will find ideal conditions on the lawn for their development. That sterilisation of the soil will deal with this is too large a subject to consider at the moment. Here is a little point so often overlooked—why is not a regular examination of the sward made so that on the first appearance of the intruder, then in its small or embryo stage, its removal is easy and certain? Weeds do not become rapidly established. In the case of a new lawn it is an excellent scheme to construct it in summer when the soil moves easily

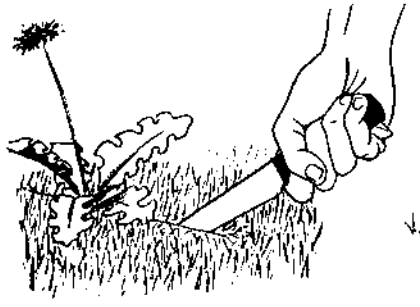

FIG. 1.

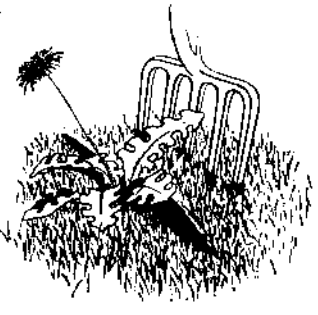

FIG. 2.

FIG. 3.

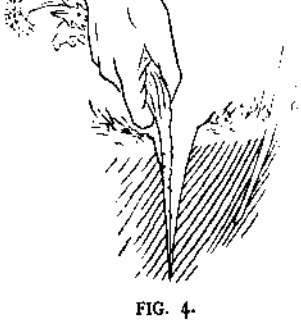

FIG. 4.

Digitized by Google

and any weed plants can clearly be detected and removed clear of the site, or better still, sent away to a recognised distant dump instead of remaining in any form near the lawn. Again, how frequently is a bare part of the lawn returfed with, to all appearance, excellent turf obtained from some distance, which looks, on delivery, free from weeds, but, nevertheless, when growing weather conditions arrive new varieties of weeds appear in our lawn, and how we wish (if close observation has been kept), that we had seeded the bare place thickly with reliable seed or exchanged it with a good piece of turf from the side of the area and then seeded the worn material in its new quarters. This goes to prove that the best preventive is to obtain and maintain a lawn consisting of a thick plant of suitable grasses.

Their Removal.

The removal or eradication of weeds from any lawn demands a methodical and well thought-out scheme of work if success is to be obtained; for example, if you wander indiscriminately over the sward selecting the largest plants, merely cutting off the tops, it will mean, in all probability, that a stronger weed plant will be in evidence next year. This proves that it is essential to remove all weeds with complete roots to stop their subsequent stronger development. It has, first of all, to be decided whether hand weeding or the use of a chemical weed eradicator is demanded and this will depend on the number and size of weeds and their proportion to the amount of useful grasses. Generally it is found that where large weeds, such as dandelions and plantains, are present they will require removal by hand and afterwards the weed eradicator applied to the smaller ones, such as daisies and pearlwort. Now, the removal or killing out of weeds is not the only thing required if we intend to obtain a good lawn—the vacated places must be sown with grass seed or other weeds will, in due season, appear, having germinated from the seeds deposited by the deposed occupant, hence we see that it is possible to have many weeds where only one was previously growing, and, while the grass seed sown will not, perhaps, completely foil this, still it does, in conjunction with the regular observation, minimise the danger. Another important item is that if a hole is the result of the removal of a large weed, such hole requires filling with a mixture of grass seed and sand, which latter should be of the deeply dug inland type. Where a small piece of turf is thickly infested with weeds, it may be best to cut it out and replace—if in the centre of the lawn—with turf from the side and seed the resultant bare patch. Frequently the decision arrived at is to remove all the turf from a weedy lawn and sow it afresh—in such cases the gravest consideration must be given to the fact that the weeds have seeded into the soil and will germinate with the grass seed; therefore, only do this as a last resource.

Various Weeds.

A weed requiring the greatest care in its removal is the common dandelion (Taraxacum Dens-leonis), and the accompanying diagrams clearly show a method practised with the greatest success. The knife ought to be of stiff steel, about 9ins. long and very sharp. Diagram I shows two cuts outwards from the plant, II and III the garden fork slightly raising the cut, which opens, allowing, as IV, the plant to be taken out with the complete root. In many cases during the autumn this pest has a small display of leaves, giving the impression that it is only a small plant, but careful eradication, as above, will often expose a thick root, which in spring would produce a large specimen. The following undesirable plants are frequently found in weedy lawns: Plantago Coronopus (buck's-horn or star plantain), which is frequently introduced by using seaside sand—it roots very deeply, because of its long tap root; other plantains are Plantago lanceolata (rib grass or hardheads), and P. major (common plantain). Achillea millefolium (yarrow, milfoil) can only be gradually removed by raking up and mowing off closely. Ranunculus repens (creeping crowfoot, creeping buttercup), and R. bulbosus (common buttercup), both require digging out. Clovers such as Trifolium repens (white Dutch clover) can be gradually checked by raking and close mowing; T. minus is amenable to hand weeding. When not too strongly established the following can be effectively removed by using weed eradicator: Rumex Acetosa (common sorrel), Sagina procumbens (pearlwort), Bellis perennis (common daisy), Cerastium arvense (mouse ear chickweed) and moss.

We may, conclude by remembering that observation, regular and correct cultivation, and not relying on a preparation of a chemical nature alone, will give the grasses the opportunity of making the perfect lawn they so richly deserve. JAMES MACDONALD.

"THE GARDEN" CROSSWORD—II

Two Prizes of ONE GUINEA will be given to the first two correct solutions opened on the morning of Thursday, December 2nd. If no correct solutions are sent in, these prizes will be awarded to the first two in order of merit that are opened. All envelopes must be marked "Crossword" on the outside and addressed to THE GARDEN, 20, Tavistock Street, Strand, London, W.C.2. No other communication must be enclosed in this envelope.

ACROSS.

1 Vegetable rich in iron.
7 Fruit used in wine-making.
11 Part of flower on which carpels stand.
12 Any small area.
14 Minute particle of matter.
15 A dried plum.
16 North Carolina (abbr.).
18 Part of a lion and horse.
19 Parched.
20 Well known timber tree.
21 Plural suffix.
22 Tone again.
23 A cereal grain.
24 New Hampshire (abbr.).
25 Plants of the cabbage kind.
27 The wild plum.
30 Hindmost.
32 Earth displaced by worms.
33 A crude hut.
35 Hawthorn blossom.
36 Shade of brown.
38 Used for roasting meat.
39 An alternative.
40 A rake (not the garden variety).
41 Used for watering gardens.
43 Ornamental vase.
45 Plant of the milkweed family.
49 Concerning.
50 Lythrum.
55 Doctor of Theology (abbr.).
56 Umbelliferous plant used in cordial-making.
57 A false step.

DOWN.

1 Male organs of a flower which produce pollen.
2 Alkali obtained from plant ashes.
3 Commonest metal.
4 Figures.
5 Like.
6 Machine for covering seeds sown.
7 Breed.
8 Fish eggs.
9 Aluminium (symbol).
10 A hardy bedding plant.
13 Pernicious.
15 A light blow.
17 Small stone fruit.
20 A mineral poison.
26 Snare.
27 Utter.
28 Another form of "Ottar."
29 Linked with "mess of pottage."
31 Fragrant oil of the damask rose.
32 A garden vegetable.
34 High school (abbr.).
35 Soil rich in decayed matter.
37 Birds' retreats.
42 A turnip (Scot.).
44 A negation.
46 Mineral rock.
47 Third note (tonic sol-fa)
48 Rear of a ship.
51 South Africa (abbr).
52 A beheaded hen.
53 Seventh note of scale.
54 Goes with 'im.

OUR SERVICE BUREAU

Though so many subjects are dealt with in each issue of THE GARDEN, *it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, there is always information available from a staff of expert contributors and consultants; and there is no charge for this. It is one of the additional means of service which* THE GARDEN *is glad to render to its readers.*

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope and the coupon, that will always be found in each issue, shall be sent with the enquiry. We would point out, however, that we cannot undertake to supply readers with plans and designs of gardens, but will willingly assist in giving suggestions for planting.

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2.*

We have selected the following enquiries, with their answers, as being of more general interest, and therefore worthy of publication.

How to Get Rid of Elm Tree Roots.

Outside our high kitchen garden wall we have a row of small elm trees almost touching the wall. We find the roots are coming right under the wall and damaging our peach and plum trees on the inside of the wall, besides dripping on them in wet weather. We want to cut the trees down, and I wonder if there is any way of killing the roots by inserting poison of some sort into them. This has been suggested to me, but I do not know if it is possible.—D. C., Godalming.

The only effective way of dealing with the elm tree roots is by grubbing them up completely. Sometimes it is advised to treat their roots either with nitric acid or saltpetre, poured into the bole of the tree, but on the whole these are of little or no avail. The trees should be cut down, and then the roots dug out. It involves considerable hard work, but the killing of the roots is assured.

A Neglected Vegetable Garden.

I have just taken over an allotment which has been tilled, but has since been neglected for some time, and now is covered with growth, grass, etc. I should be glad if you would advise me how to work it. I am a novice, and would like to make use of the growth as a manure. How should I proceed? I contemplate growing vegetables chiefly, and should like to know what could be planted during the autumn. The soil is pretty good, situation Morden. Do you think manure would be required other than the growth mentioned; if so, manure being difficult to procure, could you advise a substitute? I should be glad if you could name the vegetables that are suitable for planting now and onwards.—H. R.

Cut or peel off all surface growth and burn when dry, returning the ashes to the soil in a dry state next spring. You may heap the rubbish if you prefer this treatment of it, and scatter lime or salt on each layer, using the material as a manure next spring. Wakeley's Hop Manure will do a lot of good and take the place of manure as obtained from animals. Only cabbages, and also Brussels sprouts, can be profitably planted now. Get the ground ready for spring cropping.

Green Tomato Jam.

I have tried many times to get a recipe for green tomato jam that will stay a delicate green colour and not turn a dingy brown Can you supply this recipe? I should be extremely grateful for this yet one more helpful thing which your paper supplies.—R. H., Westmorland.

A very good recipe for making tomato jam is the following: Slice the fruits, allowing for every pound of tomatoes 1lb. of sugar, and to every 2lb. of sugar and fruit the grated rind and juice of one lemon. Put the tomato slices into a deep bowl, scattering the sugar between the layers, and leave all night. When boiling, add the lemon juice and lemon rind, and cook until the mixture clings to the spoon. A good way to keep the pretty green colour is to add a little green vegetable colouring when the preserve is nearly cold, before potting. This can be purchased at any good stores.

Shrubs for a North Wall.

You were kind enough to advise me recently as to shrubs for wall decoration, and I am acting on your advice. The north wall of my cottage in Kent is now the chief difficulty—a great blank space of concrete and cement. The soil is lower greensand made fertile, elevation 700ft. above sea-level and somewhat exposed. Would the Wistaria chinensis thrive on the north wall? The roots could be on the east or west side, and it is the higher part of the north wall which I specially wish to cover. Would wistaria need fixing to the wall, or would it cling, or how should it be trained up? I do not wish any disturbance of the cement or opportunity for a crack to occur. Would the ceanothus train well without fixing to the wall?—C. R., Bromley.

Regarding climbers for a north wall, the best self-clinging flowering climber we can recommend is Hydrangea scandens. Alternative foliage climbers are ivy and Ampelopsis Veitchii. Wistaria requires very strong supports to fix it to a wall. Ceanothus also must be firmly fastened. The best way to deal with a wall of this kind is to drive in large pins with eyeholes at intervals, through which lines of galvanised wire can be threaded. Any damage in fixing can be made good at once by a bricklayer before tying in the creepers.

Grubs in Garden Peas.

I shall be much obliged if you can give me some advice about grubs in table peas. Last year all my crops were spoiled by maggots within the pods. There appeared no sign of entrance from outside the pod, which suggests that eggs were deposited in the pea flower. The later sowings were worse than the earlier; not a pod escaping. The soil here is clay with a little chalk. Grubs also attacked the gooseberry bushes, but in this case eating the leaves. Perhaps the same treatment would eradicate both pests.—M. R., Bembridge, Isle of Wight.

You are correct as to the grubs entering the pod at the flowering stage. It is at this stage that the beetles pair and deposit the eggs in the flower, and the grubs are hatched inside the pods. Sprinkle Sanitas powder freely about the rows of the flowering plants to keep off the beetles. A light sprinkling on the plants, too, will be beneficial. Present treatment consists of trenching, throwing up the soil in big lumps to let in frost and rains, as the pea weevil lodges in the soil during the winter.

What to Plant in a Small Sunk Garden.

I want to make a sunken garden in a space 12ft. by 25ft. at the back of my house, which, with the one next door (east of mine) shades the plot from sunshine at 3 p.m. in midsummer and at 10 a.m. now. It faces east and south, and has house walls on the north and west sides. Ferns will do, I know; but I shall be grateful for suggestions as to suitable treatment and plants.—J. T., South Woodford.

In the circumstances we feel that a simple design would be the most satisfactory, and suggest, assuming that the garden will be entered by steps from the house on the longer side, that you have a border 2ft. 6ins. wide, lay imitation York paving on the remainder and place two figures or tubs on it—one at either end, midway from the side of the steps to the border. There might be an occasional shrub, such as Buxus balearica, euonymus, Daphne Blagayana, Gaultheria Shallon, G. procumbens, Erica carnea, osmanthus and yucca in the border. The most suitable herbaceous plants include Anemone japonica, Campanula lactiflora, epimedium, Dicentra spectabilis, hemerocallis (all sorts), Polygonum affine, Cimicifuga simplex, funkias, trilliums and German irises. The best alpines are Anemone Hepatica, Astilbe simplicifolia, Calceolaria polyrrhiza, Gentiana asclepiades, iberis, Linnea borealis, Oxalis enneaphylla, various primulas and primroses, mossy saxifrages and Viola cornuta.

NEW CHRYSANTHEMUMS.

ON Monday, November 15th last, the Floral Committee of the National Chrysanthemum Society considered the merits of twenty-nine new seedlings and selected the following for the first-class certificate :

AUTUMN TINTS.—This very large exhibition Japanese variety has been shown in groups several times of late. The flattish florets, which droop lightly, are of uncommon fawn colouring, which becomes tinted with rose with age. Shown by Messrs. Keith Luxford and Co.

GRENADIER.—A large-flowered single of brilliant crimson colour with a small disc. Shown by Mr. H. Shoesmith, jun.

MISS DOROTHY CAPP.—A pure white single of large size and possessing substantial florets. Shown by Mr. H. Woolman.

GOLDEN SEAL.—A splendid large single of excellent form and rich buttercup yellow colour. Shown by Mr. H. Woolman.

RED MAJESTIC.—This excellent sport from the well known large exhibition variety was seen in several leading exhibits at the recent show The red colour is very bright. Shown by Mr. H. J. Jones.

RITA.—A large single of graceful habit and bright chestnut colour with a golden shade around the zone and golden tips to the florets. Shown by Mr. H. Shoesmith, jun.

LADY BRUNTON.—A large Japanese variety of compact habit, though the flattish florets droop, and golden bronze colouring. Shown by Messrs. Keith Luxford and Co.

SCYTHIA.—An exhibition variety with long, drooping and loosely incurving florets of soft amber colour. Shown by Mr. H. Woolman.

W. RENSHAW.—Although not sufficiently large for the exhibitor, this Japanese variety has considerable decorative value. The flattish florets droop gracefully and recurve at the tips. The colour is a fascinating rosy apricot. Shown by Messrs. Keith Luxford and Co.

PUBLICATION RECEIVED.

A new and much enlarged edition of that exhaustive and standard work on garden design, "The Art and Craft of Garden Making," by Thos. A. Mawson (Messrs. B. T. Batsford, Limited, price £3 15s. net,) has just been announced and constitutes the fifth edition of this work since its first appearance about twenty-five years ago. During these years it has grown from a comparatively small manual into a volume of imposing size and now may be accepted as an encyclopædic work on the design of gardens. Full advantage has been taken by the author since the appearance of the fourth edition to rearrange and overhaul all the text and illustrations and to bring it into line with modern ideas and developments. At the same time, much new material has been added in the form of new examples of modern design of gardens laid out by the author during the last few years. Nearly all the earlier illustrations are retained and have been greatly added to in the present edition, giving the volume a wider scope. The work is illustrated very fully from water-colours, photographs, sketches, plans and measured drawings, all of which are particularly well executed. The volume is well and clearly printed and handsomely bound and would make an excellent Christmas gift for any of one's gardening friends who have large and extensive gardens or pleasure grounds. This last edition, undoubtedly, is as near perfection as any work on garden design could be.

Special cheap offer of FLOWERING BULBS suitable for naturalising purposes in Garden Walks, Drives, Plantations, etc. or for Cut Flowers.

Your Gardening Friend

uld most appreciate the choice new Broom admired by H.M. King at Chelsea, and given a unanimous Award of Merit the R.H.S., as well as highest distinctions on the Continent. e New Crimson Broom "Dorothy Walpole" is the most markable variety ever seen—colour rich velvety crimson—is as hardy and vigorous as the common Broom of the hillsides d will flourish in ordinary garden soil in any part of the itish Isles, however far north.

AT this season of the year one's thoughts run to presents for family and friend. Have readers thought of the pleasure that a gardening present will bring to anyone who is interested in plants and gardens? Nowadays the fashion has come in to give something useful as a present, an admirable idea, and what could be more useful than something for the garden? It can take any form from a fertiliser to a tree, but whatever it is you may be sure that it will be welcomed by a gardener. After all a garden is little different from a bookshelf; in the one you collect plants, in the other books. The best Christmas present we can suggest for a gardening friend, one which will be most useful and one which will afford him much pleasure the whole year round, is that of a year's subscription to THE GARDEN.

General Purpose Gifts.

THE gardener, like anyone else, will welcome gifts of a general nature, as well as those applying to his particular hobby, and what would be a more suitable present than a pipe or a box of cigarettes? Almost every gardener is a smoker. Indeed, smoking adds greatly to the joy of gardening and to the discussions which centre round this plant and that plant on a summer's evening. It is not an expensive gift and one which is sure to be appreciated. There are any number of brands of tobacco and cigarettes as choice, but smokers are conservative in their tastes and it is on the whole better to restrict your gift to such a well known brand as Players. If your friend is not a smoker, then a gift of another kind, which is both novel and useful. A novel present is generally more appreciated, especially if it can be made to serve a useful purpose. Rather a novel present will be found in the Spade Boot Scraper. It is especially useful where there are many visitors to the garden, as it ensures that no mud or dirt adheres to the boots or shoes on entering the house. It can be fitted near the entrance of the house in a prominent position so that visitors will not pass it by. Fitted with a scraper on one side and a brush on the other of an upright standard, it is a neat little asset to any garden and is sure to be much valued. A variation of this type of scraper has recently been put on the market, which will make a useful present to any of one's gardening friends who are motorists. It is a scraper to be fitted on the footboard of the car to ensure that no mud is taken into the car. Still another present which a lady gardener will much appreciate is a mat for kneeling on when weeding and doing odd gardening jobs. There is one mat, known as the Kneel on Air Mat which is excellent for this purpose. It is exceedingly comfortable to work on. It is a present which is both novel and useful and one which will be greatly valued by any of your gardening friends. Then, again, all gardeners will find a use for a gardening diary for next year, and there is no more useful one published than the "R.H.S. Gardeners' Diary." It is invaluable to all interested in the garden, containing weekly instructions of seasonable work to be done, and many gardening hints. It is inexpensive and makes an ideal Christmas gift.

Trees, Shrubs and Fruit.

TREES and shrubs make welcome presents, all the more so as they are lasting and will call to mind the donor for many a year to come. It may be that you know the taste of the individual to whom you wish to give the gift; in that case your selection will be

Farrer's Last Journey
UPPER BURMA, 1919-20
By E. H. M. COX

Demy 8vo. with 28 illustrations from photographs by the author.

All lovers of the writings of the late Reginald Farrer will delight in this account of Farrer's expedition of botanical exploration to the wilds of Upper Burma. It has been written by his companion of the first year, and in it will be found not only descriptions of this paradise of flowers, but also long extracts from Farrer's letters and articles. It is a book for all who are interested in any branch of horticulture.

easy. He may lack a particular apple or pear that will suit him, or it may be a shrub or tree for some special spot in the garden that still remains to be filled. Best of all, however, is a surprise gift of some admirable tree or shrub of which he may be in ignorance, for there is an added pleasure in growing something unknown and untried, the pleasure of expectation. Think of what you have seen out of the way in some garden or another that appeared to you to be a worthy plant and give it as a present to someone whom you know will appreciate it.

It is impossible to give individual suggestions in a note of this length, but there could be no plant more acceptable to those living in lime-free soils than a fine hybrid rhododendron or some new azalea, for here are plants that are glorious in their colour. Others that would make an admirable gift are several heaths, flowering cherries, an ornamental maple, viburnums, berberis or some conifer like Cedrus atlantica glauca, or a dwarf Juniperus hibernica for the rock garden. Then we must not forget our national flower, the rose. Some variety or species that a friend or relation may lack makes a most acceptable gift, for every one grows roses and all appreciate their beauty. Although a tree or shrub cannot be tied up in tissue paper and decked with ribbons, or, indeed, plunged into the Christmas stocking, yet they do make admirable gifts.

Garden Furniture.

ARE you thinking of buying some piece of garden furniture for one of your gardening friends? If so, here are a few suggestions. A garden seat is mentioned first as being the most useful of all pieces of furniture. The very best are made in well seasoned teak wood, such as that taken from old battleships, and one can rely on the finest workmanship being used in the making of seats of this wood. The cheapest teak seat of 4ft. 6ins. in length costs about 3 guineas. Tables, benches, folding and arm chairs are all made to match and one of the most attractive of presents is a garden suite which consists of a square table and a set of four armchairs. The chairs fit compactly round the table. These suites take up very little room, are solid, well made and need no painting or varnishing to protect them from the weather. Plain oak seats are also obtainable.

White painted seats, tables and chairs are most attractive. One of 4ft. 6ins. long, made in the old English style, costs 70s. Semi-circular seats are rather out of the ordinary and therefore might make a greater appeal. Besides the types of chairs and tables already mentioned, light and portable garden chairs and lustre furniture made of osier might meet with high approval. The latter kind of furniture is ideal for the week-end cottage, or for carrying about from one part of the garden to another. Its brown colour harmonises well with its surroundings in the garden, it does not need varnishing and is very inexpensive, in fact a set of four armchairs and a table can be purchased for the small sum of 45s.; while £7 will buy a summerhouse which can be erected within a few minutes. There is a special children's summerhouse and small-sized chairs and tables, which would be received with great joy by any child. They are so light that quite a small child can move them about.

Some of the most comfortable of all garden chairs are those made of sea grass; they are soft, pliable and do not possess that habit of creaking every time they are moved. Most of these chairs are made so that they fold up and so can be stored away in a small space. Your gardening friends could not fail to appreciate one of the comfortable sea-grass armchairs, the cost of which is about £2. Another idea is a tent umbrella, or even a deck chair. Any one of these pieces of garden furniture will surely be greatly appreciated, for they are novel as well as useful.

Nurserymen, NORWICH, NORFOLK

Established 1869.

Notes from Maidstone.

COOKING APPLES.

All Apples may be cooked, but not all are edible. Some are pasty and flavourless, others brown and woody. We can thoroughly recommend Golden Noble for autumn use, this cooks a clear amber yellow, and Thomas Rivers, in use till December, of unique fragrance. Of these, beside the usual forms, we have some extra large pyramids, 6ft. high and well developed, at 15/- each.

George Bunyard & Co., Ltd., The Royal Nurseries, Established 1796. Maidstone.

Box—Green and Variegated, 3 to 8 ft.
Hollies—Common, 5 to 8 ft.; Variegated and Green varieties, 2 to 6 ft.
Thuiopsis borealis, 10 to 12 ft. Cupressus Lawsoniana, 12 to 14 ft. Cedrus atlantica glauca, very fine, 14 to 16 ft. Osmanthus, Phillyreas, Spireas, Lilacs, Viburnums, etc.

GOLDEN YEWS

A Magnificent Stock in all shapes and sizes from 2 to 10 ft.

PRIVET, Common and Oval-leaved. **QUICK** and **HORNBEAM** for Hedges.

AZALEAS, in great variety, 2 to 5 ft.

RHODODENDRONS, without doubt the finest stock in the trade of named varieties, 2 to 6 and 8 ft.

HARDY HEATHS in great variety and a good general nursery stock.

Catalogues ready.

Enquiries and Inspection invited.

THE GARDEN

VOL. XC.—No. 2870. DECEMBER 4, 1926. PRICE TWOPENCE.

NOTES OF THE WEEK.

The Gardener's Log-Book.

PROBABLY most gardeners keep a note-book of some sort, though there are many who would scorn to admit it. That being so, it would be just as well to put this on an organised and systematic basis, which can best be done by keeping a diary. Although the New Year of the calendar does not represent the beginning of the gardening year, it seems to be as good a time for starting a diary as any. The gardener who relies on his memory alone is often at a disadvantage as compared with the man who can refresh his memory from his diary and can thus be quite positive on the point in question.

A diary should contain primarily a record of the daily work performed, but if it contained nothing else it would be of little value. In many cases the record of one day would be but a repetition of the doings of the previous day, and this would be neither instructive nor interesting.

Beyond a record of the daily happenings the diary should show all that is done in the garden, and all observations on the progress of the crops. It should be a daily bulletin of the condition of the garden, so constructed as to form a complete history.

In a well kept diary it should be possible to trace any one subject from the preparation of the soil to the end of the season of use of that particular vegetable or flower. This is rendered more easy if the diary is indexed, which is no very easy matter. It is useful in order to be able to refer quickly to a particular subject, to leave margins on either side of the sheets and to mark in them the names of the fruit, vegetables and flowers dealt with in the body of the diary. One can then more easily see by glancing through the book any particular item.

A well kept diary should show: when the soil was prepared, the crop that preceded it, the method of preparation, the kind and amount of manure used, the date of seed-sowing, the variety sown, the amount of seed used, the time when the seedlings first appeared above the surface, the times of hoeing, thinning and top-dressing, the pests encountered, the method of controlling them, the success or otherwise attending this, the date when the first dish was available, also the last and any other item of work done; together with many observations made during the course of growth. In the flower garden there would be still greater scope for the record of observations, such as the colours, the heights, the habits, of the different varieties, and a wealth of valuable information which no book could give, and which none but a superhuman brain could hold, in a readily accessible form.

The keeping of a log-book is no easy matter, if it be posted up religiously every day. During the winter there is no difficulty, but during the busy months of spring and summer it is likely to be regarded as a drudgery. It should be no more of a drudgery for the gardener to keep a diary than for a business man to keep his books. Never on any account let it slide for as much as one day, for a diary with omissions is of no real value in the future.

Wet Weather and Drainage.

THIS wet autumn has proved conclusively the value of efficient drainage in the garden. Those that are well drained are workable after one or two days without rain, while it may be weeks before those that lack drainage are in a fit state to work; in fact, quite a large percentage of gardens at the present moment might be called water-logged. It is true that heavy soils, particularly clay, are difficult to drain, but readers should make every effort to accomplish it. It is easier to conserve moisture in dry weather by mulching and efficient hoeing, than to remove surplus moisture that undoubtedly does harm to many plants. The roots become sodden with constant soaking and so become an easy prey to fungus and insect pests.

In small gardens the actual laying of drains is not only troublesome and expensive, but there is an added difficulty in that it is often impossible to find a suitable outlet for the surplus water. When actual drainage is difficult or impossible, a great deal can be done towards mitigating the collection of too much moisture in another season by intensive cultivation of the soil, particularly in new gardens. This should be done to a considerable depth so that the earth near the surface, in which most plants root, can be thoroughly broken up and loosened. In any case we cannot impress too strongly on our readers the importance of drainage in the garden. It means much to the well-being of your plants.

HAVE YOU

- *Cleared out all dead and decaying wood from your shrubbery and raked over the soil?*
- *Protected your autumn sown beans and peas by drawing up a ridge of soil round them, and dusted them with soot?*
- *Pruned your grape vines and renovated your exhausted vine borders?*
- *Lifted the roots of your late border chrysanthemums and placed them in a frame?*
- *Protected with hand lights your Christmas roses?*
- *Renewed the labels in your rock garden and herbaceous borders?*
- *Lifted the remainder of your cauliflowers and placed them in a cool shed? They may otherwise be spoiled by hard weather?*
- *Started to propagate by cuttings your greenhouse chrysanthemums?*

RESULT OF THE NOVEMBER "GARDEN" COMPETITION.

THE Michaelmas Daisy Competition has obviously proved popular among many of our readers from the number of entries sent in. The number of varieties mentioned, no fewer than 117, is astounding, but there is no doubt about the voting on which are the six most popular. They are:

King George.
Climax.
Little Boy Blue.
Barr's Pink
Anita Ballard.
Perry's White.

Over fifty votes separate the first from the second and over thirty between the second and third, but the first four are close in comparison to the drop between the fourth, fifth and sixth. Many readers may be interested to know the next six in order of merit. They are: Nancy Ballard, Beauty of Colwall, Ethel Ballard, King of Belgians, Snowdrift, Sam Banham. It will be noticed that several of the varieties are comparatively new which proves how quickly merit in Michaelmas daisies is recognised.

No reader gave the first six. The first prize of three plants of each of the first six is awarded to Mrs. W. J. Stewart, 46, Dunbar Road, Birkdale, Southport, who gained top marks. The second prize winner is Miss M. Mason, Leighton, Parkgate, Cheshire. The third prize is divided between Mrs. Mack, Swanmore, Bishop's Waltham, Hants, and Mrs. F. J. Roskruge, Bosvean, St. Ives, Cornwall. To all the prizewinners the plants will be despatched in due course.

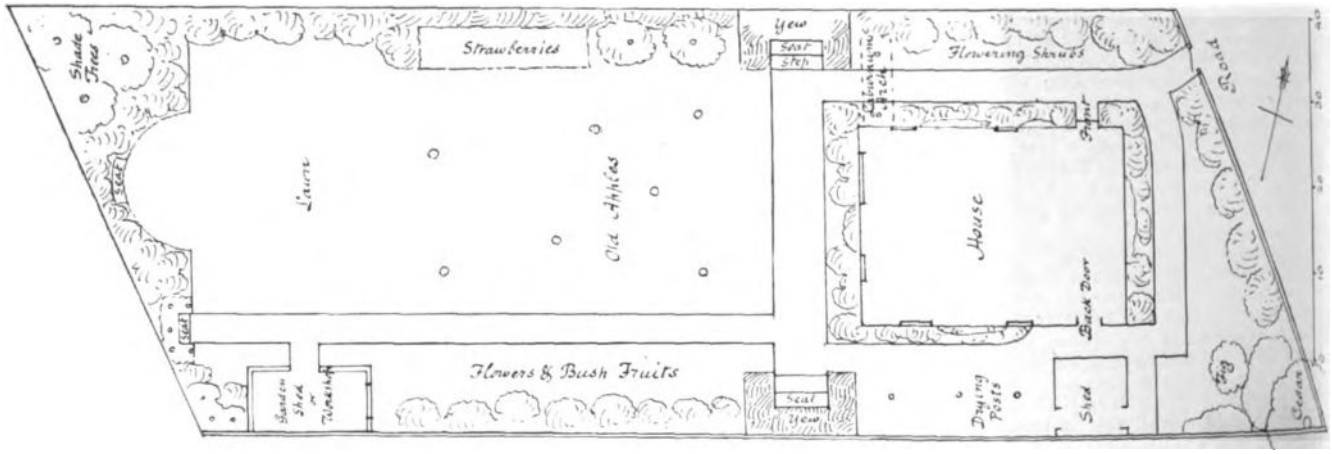
THE JOY OF MAKING A NEW GARDEN

BY GERTRUDE JEKYLL.

A HOUSE is building on one of the usual narrow-shaped plots near a small country town in lower mid-Sussex. A 6ft. wall encloses the land next to the road and a 5ft. wall is the boundary on the south side. At the south-east corner there is a cedar, and near it a standard fig, both shading the ground a good deal and presenting one of the most frequent, and often considered insoluble, problems to the planter—that of knowing what is likely to thrive under such conditions. One of the things most willing to do well in such shade is Berberis Aquifolium, though not actually up to the bole of the cedar, and the common holly will thrive under the outer branches. Then, in such a place as the foot of the wall, near the entrance to the shed, is just the position for the common male fern (Lastrea Filix-mas). For a continuation of planting against the front wall nothing can be better than laurustinus, and for suitable flowers between that and the house there are columbines, foxgloves, phloxes and Solomon's seal, all thankful for some shade. The spaces beyond the shed will be handy for some drying posts and lines, and the place is well screened from observation. The entrance path takes a little turn just inside the gate, where laurustinus could well be planted on both sides, followed by a continuation of flowering shrubs to show from those of the living-room windows that are on that side. A pleasant incident can here be made by planting two standard, laburnums trained to form an arch over the path; giving a long vista through to the farther ground.

On the garden side it is always desirable to have one wide path with some definite ending, such as the seats at each end, closely sheltered by a planting of yew. These, when well grown, can in time be trained to form a complete hood over the seats, one of which will be pleasant for summer shade and the other for a winter suntrap. It much helps good effect and is also well for dryness underfoot, if the seats stand on a low step, about 4ins. above ground.

The place was formerly a kitchen garden and some old apple trees remain. The owner is partly disabled and cannot do heavy digging. He therefore wishes to retain the apples and to let the ground beneath them and the space beyond be a quiet lawn. The semi-circular shaping at the end will give an effect of refinement and good design. A seat here will be in complete shade and will give a pleasant view of the grassy space and the old apples. Beyond the boundary at this end is a grove of trees. If three good trees for shade are planted in the north-west angle with a shrub planting, fairly tall, at the back of the seat, mostly evergreen, the dividing fence will be concealed and the farther trees will look as if they belong to the place. From the seat in the semi-circle, forwards for about 30ft., the grass should be kept mown; under the apples it should be left uncut till the middle of June to allow of having planted in the grass groups and drifts of daffodils, fritillarias and bluebells, with their near relatives, the Spanish squills, whose foliage would be ripe by the middle or end of the month; then another cutting about the middle of September, will leave the grass fairly short for the time of apple gathering. A bed for strawberries is desired and is shown in the most suitable place. The path on the south side of the lawn already exists. Across this path from the apples will be the place for some flowers for cutting and for enjoyment, perhaps grouped with some small fruit bushes. Some such structure as the garden shed may be in future contemplation; in any case, some place for tools is wanted, and the corner beyond would be a convenient rubbish place. An arbour of the useful tea-tree (Lycium chinense) will make a fitting ending to the path.



THE IMPORTANCE OF DRAINAGE IN THE GARDEN

AN excess of water is sometimes a potent reason for a soil being unproductive. Among other things it lessens its capacity for holding air, and at the same time renders the necessary gaseous exchanges more difficult, and the plants suffer from an insufficiency of free oxygen.

Water-logged soils have been rendered productive and many others have had their fertility increased by drainage. In carrying off the superfluous water the soil becomes drier and consequently warmer, allowing seed to be sown earlier and the produce harvested sooner. It enables freer access of air to the soil, increased root activity and greater ease in working. The details of how I drained a certain garden may be of interest to readers.

It was found, by the use of "boning-rods," that the difference in levels between extreme points in this garden only allowed of a fall of 4ft. in 230yds. A straight-edge 15ft. in length had a small block of wood 1in. in depth nailed to its edge. Fireclay pipes 4ins. in diameter were used for the main central drain, and the straight-edge with the spirit level were used on every fifth tile put down. A double-branched fireclay pipe was put in at every 18ft. to admit flow from branch drains. These were 3in. diameter tile drains.

The minimum depth of these was not less than 2ft. 6ins., to allow of trenching the soil 2ft. The fall at the deep end varied according to depth of main drain, and each drain had a covering of rubble or ashes over the tiles. By leaving the lower end of the system open a rainstorm assured us of the efficiency of the work done.

Many and ingenious are the methods of drainage employed in allotments where permanence of holding is not assured, and in most cases giving effective results. The area given over to allotments I have in mind was a stiff, low-lying clay which it required little knowledge to know would be benefited by drainage.

The work was undertaken with great enthusiasm animated by the reflection that once the job was done the rest would be comparatively easy and good crops result. There being no natural outlet for the disposal of superfluous water, the task of drainage was neither easy nor pleasant, as a considerable amount of excavation had to be done.

In most cases the formation of a "sump" to collect the drainage water was the sinking of a large water-barrel at the lowest or most out-of-the-way corner in the allotment. The utility of such a proceeding was evident in a situation where water was required to be brought some distance when needed.

The plan of drainage mostly favoured was the "herringbone" pattern—a main central drain with short offsets. And the average depth of drain level was not less than 2ft. and not more than 3ft., to lessen the work of excavation and allow of trenching the soil. The material used for drainage was of various kinds, but "clinkers" seemed to be favoured, being got at little cost from a neighbouring dump. These were roughly sieved and the largest placed in the bottom, with the fine on top to form the drain.

One ingenious "holder" had been able to procure a number of small cylindrical cases used for packing shells, out of which he knocked the ends and used these in place of tiles. Another made use of some creosoted boards sawn into suitable lengths and placed in triangular form in the drains. A little space was left between each of the side boards to allow the water to find its way into the drain.

WM. MCCARRELL.

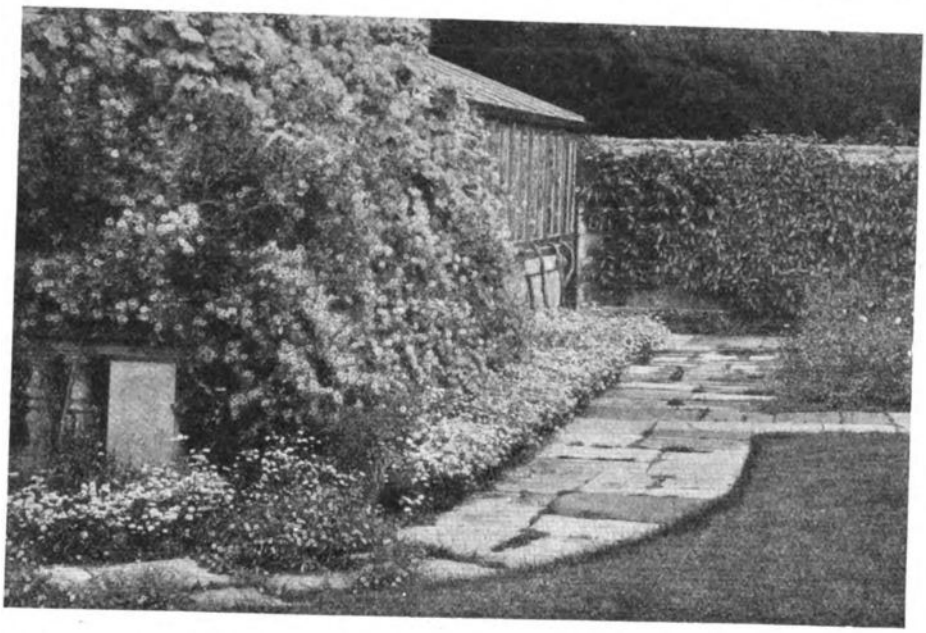
TRAILING PLANTS WORTH GROWING

Free use should be made of those plants which have a creeping or trailing habit. Some are admirable for the rockery while others again are eminently suited to form edgings to path or border.

PLANTS which have a procumbent or trailing habit have a place in every well ordered garden, and when properly grown and established, are not the least pleasing feature. In hardy subjects we have those which are eminently suitable for rockeries, stone walls, window-boxes and vases. Most of them are free in growth, so that the young plant of one year has so developed by the following season as to cover most, if not all, the space assigned it. All can be put in their quarters in spring. For the rock garden or rockery I suggest:

Helianthemums (sun roses) in various colours. Three good sorts are roseum multiplex (double rose), Golden Queen (yellow single) and apenninum (single white).

Saponarias (soapworts), trailers of rapid growth, and are never better served than when, at planting out time, pieces of rock or stone are provided for them to roam among. S. ocymoides splendens has large rosy crimson flowers. There is a white and a pink form also.



CANDYTUFT (IBERIS) MAKES AN ATTRACTIVE DWARF EDGING.

AUBRIETIAS ARE SUITABLE EITHER FOR PATCHES IN THE ROCK WALL OR FOR EDGINGS.

Alpine Phloxes are very attractive when they can be given a "promontory" in the rock garden over which the shoots can depend. Prolific with their blooms, they will last in good condition from April for a couple of months. Setacea (fleshy pink flowers), atro-lilacina (deep lilac) and nivalis (white) are representative of this interesting section.

The above plants never do better than when given a fairly light soil in which sand is found, and the position should be a sunny one. Propagation can be effected from cuttings after flowering, or, which is more simple, a few of the shoots layered and then cut away in the autumn when rooting has taken place.

Gypsophilas.—These are both lime and sun lovers, and in planting them care should be taken to incorporate with the soil old mortar rubble should it be deficient in lime. G. cerastoides, a true trailer bearing a profusion of white and violet streaked flowers; G. repens, also a white; and G. rosea, a pink form, is attractive.

Lithospermum prostratum (Heavenly Blue) blooms most profusely for several months from the middle of May. Likes a sandy peaty soil and the sun, but is not averse to a partially shaded position.

Aubrietias (rock cresses), very popular everywhere, filling various positions in a garden and, once established, bloom abundantly, whether grown on a rockery and allowed to ramble or in the crevices of a stone wall, they are a sight in spring, and never fail to charm. Of the many beautiful sorts to-day are Dr. Mules (violet-purple), Fire King (crimson), deltoides cilicica (pale blue) and Daisy Hill (crimson). Gritty soil, a well drained and sunny place best suits the rock cresses. Easily propagated from cuttings after flowering.

Corydalis lutea.—A fitting plant for the chinks and crevices of a stone wall or sloping bank, flowers yellow and borne in profusion throughout the summer.

Iberis (candytuft).—An old garden favourite. A prostrate-growing shrub-like plant never better placed than on a raised position on a rockery. I. correæfolia has heads of pure white flowers.

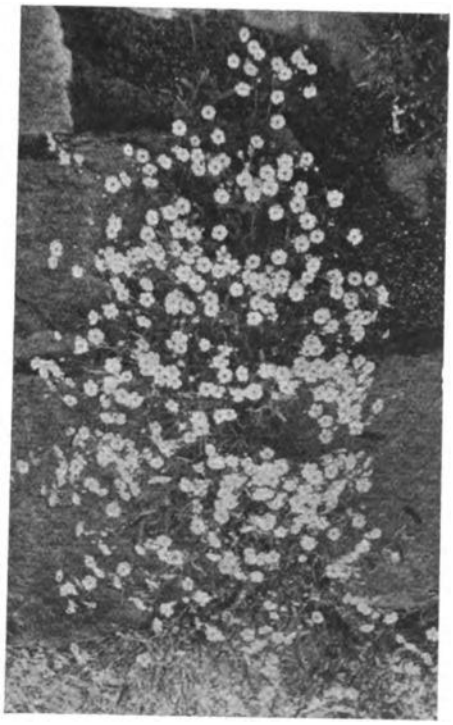
Verbena chamædrifolia.—Flowers of a telling scarlet during many weeks in the summer. Loves a sandy soil and a sunny position. Not hardy in every locality, but is worth trying.

Silene maritima fl. pl.—This is noted for its dense spreading foliage, which carpets the ground The blossoms, borne in profusion, studded among the leaves, are like those of a small double white pink. It flowers from June to September, and propagation may be effected by division of roots. Spring is the best time to plant. A sunny position is essential.

For a shady place, *Veronica repens*, one of the dwarfest of the speedwells, should not be overlooked; It is suitable for moist positions. Flowers are bluish white.

This is but a small selection of plants of a trailing habit which amateurs making a beginning will find little, if any, difficulty in succeeding with, and all of them bloom most freely.

W. F.



THE DAINTY GYPSOPHILA REPENS GROWING HAPPILY OVER A DRY WALL.

EMPIRE BULBS

THE STRIKING ADVANTAGES OF A NEW ENTERPRISE.

BRIEF reference has already appeared in print concerning "Empire bulbs," which have on various recent occasions figured both in the "dry bulb" and the flowering state in Mr. Amos Perry's exhibits at the Royal Horticultural Society and elsewhere. The time is opportune for something more than casual mention of the fact that liliums and other choice subjects are flowering from bulbs received from far-off New Zealand, for the experiments thus far conducted have shown results which not only justify an immediate extension of operations on the lines of Empire trading in bulbs, but have already revealed possibilities of extending the flowering season of some of our choicest and most desirable bulbous flowers to an extent of far-reaching importance to British horticulture.

An excellent example is afforded by that most serviceable and beautiful flower Lilium Regale, which, happily, is one possessed of a constitution and good nature which enables the inexperienced amateur, as well as the expert, to grow it with success.

A consignment of Lilium Regale from New Zealand reached Mr. Perry's nursery in June. The bulbs were in excellent condition and were immediately planted in the open. Although these bulbs were quite dormant in June, when our established bulbs were in full growth, and even in bud, the warm condition of the soil and atmosphere started them so rapidly into growth that by the latter end of September and early days of October the plants carried a brave display of fine trumpet flowers. It is a matter of real importance that the opening up of this new source of supply of bulbs thus enables us to prolong the season of the lily, and adds to the variety and charm of our flower borders right through autumn's waning days.

Another excellent lilium which has always been classed among the difficult gems of this glorious family, L. Wallichianum superbum, arrived in May, and this also has grown with quite unaccustomed vigour and flowered at the beginning of October.

The crux of the matter is this—bulbs from our customary sources of supply have reached us in midwinter. They required immediate planting, but our soil at that season is at its coldest temperature and our weather at its worst. Prolonged storage weakens vitality, and winter planting involves hardship upon the bulbs and even serious risk of loss through decay. The May arrival of the New Zealand bulbs finds our soil in most favourable condition, and atmospheric conditions fast approaching the ideal; hence rapid, unchecked growth, and successful flowering just when we are glad of variation from perennial asters and chrysanthemums.

Australia, too, is taking a part in the Empire production of bulbs, and Mr. Perry has flowered a series of watsonias, the beauty of which excels any preconceived notion of this chaste flower. Watsonia Ardernei and W. rosea are both lovely flowers, but in the series referred to there are superb varieties which embrace buff, apricot and flesh pink, real salmon and the shade we have of late grown accustomed to term "prawn red." These varieties, all from one source in Australia, bear the familiar names of Australian towns, and a trio of the best are Melbourne, Sydney and Perth.

There is a wonderful future for these flowers when they become known and reasonably plentiful. It need only be remarked that in addition to glorifying the garden in autumn these Empire bulbs will provide new material with which to embellish conservatories and greenhouses even until Christmas, and the commercial producer of choice cut flowers will surely find great utility in these subjects, which, with a little exercise of skill, he will be able to bring into service at a time of short supplies without the necessity of a deal of artificial heat. L. A.

FERNS IN THE ROCK GARDEN

MOST of the dwarf hardy ferns are naturally rock haunting species, and when one considers that fact, together with the peculiar charm of these plants, it is the more surprising that the rock gardener does not make more use of them. Practically all of them delight in shady crevices where comparatively few flowering plants will prosper. They are very easily grown, absolutely slugproof and the evergreen species are not less delightful in winter than they are in summer.

The spleenworts are among the most attractive of the smaller ferns, and the common kind (Asplenium trichomanes) is as pretty as any. This likes shade, but it is by no means averse to a good deal of sun. As for the little wall rue (A. ruta muraria), this will thrive in the hottest of walls, and the much taller, very elegant, black spleenwort (A. nigra), will also do well in quite sunny aspects. The scaley spleenwort (Ceterach officinarum) another native, is an allied species of the utmost charm, making compact rosettes of its olive green, blunt-lobed fronds which are felted with orange-brown on their under sides. This fern has a distinct partiality for old mortar and a cool site.

A favourite rock-garden fern with me is Cysopteris fragilis. It makes tufts of daintily-cut, pale green fronds about 6ins. high and soon becomes naturalised. Those who aim at a winter effect in planting ferns will do well to note that C. fragilis is, unlike the spleenworts, quite deciduous, but the delicate beauty of its spring fronds makes full amends for this. A cool chink among the most dwarf kinds should also be found for the hoary little Woodsia ilvensis, which seems to be more easily procured from the nursery than its mountain home. Nor can Allosorus crispus, the beautiful parsley fern, be overlooked. This is not really difficult to please if given a diet of a very little old leaf-mould and a generous helping of broken-up slate. Press its roots into this on a north side, place a stone on them, almost covering the crown.

A PLEASANT ASSOCIATION OF FERNS AND RAMONDIA.

and the parsley-fern will generally respond quite cheerfully.

That familiar native Blechnum spicant, ranks high as a rock garden fern, for its bright, evergreen narrow fronds, a foot or more in length, droop in a most graceful manner and there is scarcely a spot in which it will not do well. There are many crested and other varieties of this in the lists, but in this regard it has to give place to the popular hart's tongue whose varieties are innumerable. This latter is also an ideal rock garden fern, clinging to a vertical crevice with the greatest tenacity, and when growing in such impoverished conditions it rarely gets too big even for quite small gardens. With me the hart's tongue "seeds" freely both in sun and shade. It is delightful with ramondias, Linaria pallida and other lovers of sunless spots and it is practically evergreen.

The common polypody, which is at its best in the winter, is by no means to be despised, and both P. calcareum and P. cambricum are well worth a choice place. As for P. Dryopteris, our comely little oak fern, this is so refined and elegant that its gentle fronds of 4ins. to 5ins. are exquisite growing on the flat along with, say, Anemone Hepatica, or some other early bloomer which is never disturbed. P. Phegopteris, the beech fern, has much of the same delightful and tender grace and, like the foregoing, should be screened from hot sun.

For carpeting, care being taken that it does not overrun less robust and more precious things, Lomaria alpina is a little fern of the utmost value. It makes a dense mat of its deep green, short, leathery fronds, and these, both in spring and autumn, are suffused with a flush of bronze-red. In the Klondike variety of Adiantum pedatum, we have a really hardy and most beautiful maidenhair which should be given a "pocket" roomy enough to allow elbow room of 18ins. or so with some shelter from cutting springs winds. A pretty effect may be achieved by planting this lovely species at the back of the space with a colony of oak fern in front of it.

The best compost for these rock-garden ferns is old black leaf-soil with a little sand mixed through it. Planting should be done with a rather light hand, the bed or crevice being somewhat loose and friable. Any pressure needed at the roots is best attained by placing on the latter, when partly covered, a few pieces of sandstone or porous brick. Most ferns seem to enjoy broken-up slate and if this is used with the leaf-mould in place of sand so much the better.

A. T. JOHNSON.

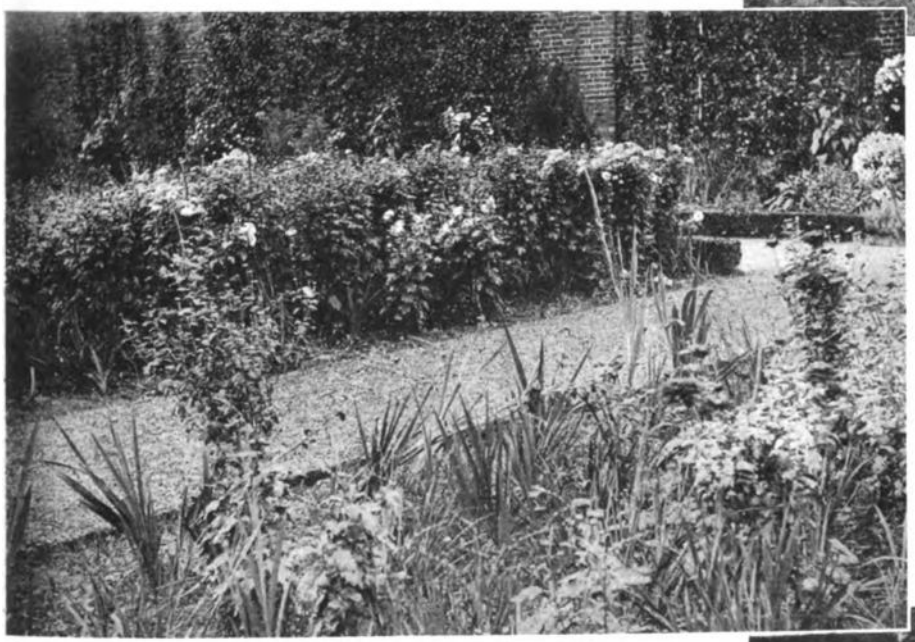
HINTS ON PATH-MAKING

This is the time of renovation and remodelling of the garden. Garden paths call for attention and treatment, and the following suggestions on the making and decoration of one or two different kinds may prove helpful.

THOSE who are garden-making may find the following hints on paths useful. In my neighbourhood gravel is difficult to obtain and expensive; the making of paths, therefore, presents difficulties. A good hard path right through the kitchen garden was necessary, and I, therefore, made one of available material—rubbish, crocks, stones, etc.—and covered it all with cinders and ashes. In September of last year I opened a drill down each side and inserted cuttings, with heels, of santolina (lavender cotton), closed the drill and pressed the soil firmly. In the spring I planted pansies 2ft. apart down each side. Every cutting took root and the "Santolina Path" has been one of the pleasures of the year—the ash-coloured path bordered with a misty greyness bespangled with purples and bronzes has been really beautiful, and one great advantage is that slugs do not apparently like the scent. The plants have grown so well that two shearings have been necessary to keep the border close and shrubby. The path is long and has 170 plants each side; I am now busy with other similar edgings—all from three plants at 6d. each bought two years ago.

Another path that had to be made was one over grass. Gravel would have been ugly besides making two more edges to be cut. I therefore made cement blocks (sand, cement and water) 3ins. thick, shaped them in seed-boxes, and sunk them in the grass, corner to corner as seen in the illustration. The result is useful in all weathers, and the grey stone in the green grass effective in all lights. E. G.



NOTHING CAN BE MORE EFFECTIVE IN ANY GARDEN THAN A GRASS WALK WITH BORDERS ON EITHER SIDE.

The Value of the Grass Path.

AS a path on which to walk, grass has a definite value in being one of the most permanent and easily kept—that is, if it is well laid in the first instance. I would like to emphasise the importance of the latter proviso. A grass path must have a well drained yet firm foundation—perhaps more so than any other style of pathway considering the fact that turf is a most porous material, holding water to a large extent; yet, if well drained, turf is as substantially dry to walk upon as stone or gravel may be. To ensure this a firm foundation is also essential, and a very level surface.

Given these conditions and the grass kept very short, the grass path will be found as convenient to walk upon after a spell of wet weather as any other kind. There is no more unpleasant moisture in a grass path than there is in one made of gravel, in this connection.

A drain is essential, and, upon this, well rammed material, preferably also of a nature that facilitates escape of water. Then the perfectly level surface must be made, upon which turves are laid or soil placed and seeds sown.

There is one important advantage concerning drainage about a grass path, and that is the fact that it can be elevated above the surrounding garden and be kept isolated therefrom, the sides of the path, cut perpendicularly, forming a sort of ditch between path and garden into which all surplus moisture quickly drains, keeping the path actually "high and dry." This also prevents encroachment of grass upon the garden soil—one of the great nuisances attending a grass pathway.

A grass path should be made up of the finest grasses, either in turf or by means of sown seeds; and the mower should be well employed and a close velvety surface encouraged. It will be found that, unless heavy traffic goes over the path—the grass will not wear badly under the tread of many feet if it is kept in good condition by cutting and rolling, and is given a good start by not being put into use for a considerable time after it is made up. Otherwise, the grass path should be left out of calculation altogether, for it will be a failure. H. A. D.

A PATH OF CEMENT BLOCKS SUNK IN THE LAWN IS BOTH NOVEL AND ATTRACTIVE.

A HARD-WEARING PATH OF CINDERS AND ASHES SUITABLE FOR THE KITCHEN GARDEN.

It can be made most decorative by the planting of suitable edging plants, such as santolina, as in this case.

THE FLOWER GARDEN

Sternbergias.

IT is rather curious that with all that is written about bulbs at this time of the year, one hardly ever sees a reference to the sternbergias. You may search the ordinary bulb catalogues in vain for a mention of them. Rarely does one come across them in the gardens of one's friends. Though I am not going to pretend that they are plants of any very particular beauty, they have an interest all their own. It is recorded that Clusius and Parkinson cultivated several of them in times long gone by.

They were named after Count Sternberg, a German botanist, and have flowers which resemble the crocus or the colchicum, yellow in colour and about the same size as the colchicums, but much firmer in texture than these and therefore more able to withstand the vicissitudes of our uncertain climate. Sternbergia lutea is Parkinson's "Great Autumn Daffodil," and it throws up its large yellow flowers together with its big leaves in the autumn. This species grows in profusion in the sheltered valleys of Palestine and on this account it has been suggested that they may possibly be "the lilies of the field" to which reference is made in the Bible. Then there is S. colchiciflora, which also flowers in the autumn, but has the additional attraction of fragrance. It comes to us from the Crimea, where it grows in such abundance round about the shores of the Bosphorus that it is said positively to perfume them when in bloom. Though most of the sternbergias are autumn flowering there is one species, S. Fischeriana, which produces its flowers in spring and is worth mentioning on this account.

Sternbergias do not appear to be difficult things to grow, though they require to be well established to bloom well in our gardens.—EDWARD CAHEN.

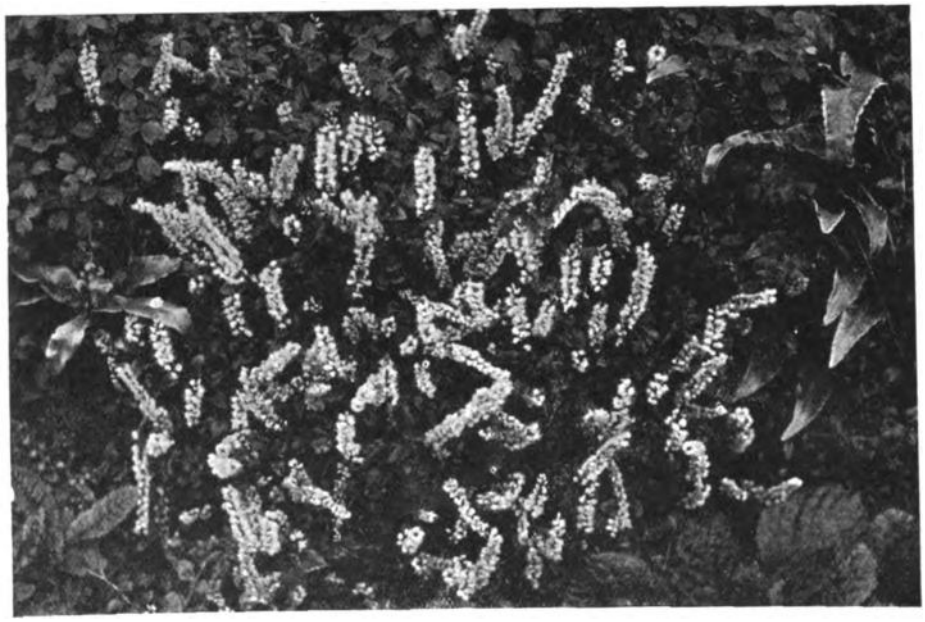
The Prickly Heath.

THE varieties of Pernettya mucronata or prickly heaths are dwarf evergreen shrubs of a few feet in height, and they are among the best of the berry-bearing plants to be found in a garden. For this reason they deserve consideration. The ornamental sprays of white berries which are freely produced are decidedly handsome. Furthermore, birds do not appear to take them. In addition to the form bearing white berries, there are others with red berries, and various shades of pink, altogether an interesting group. Among them will be found atrococcinea, atropurpurea, lilacina, nigra and alba.

They are quite hardy, and will thrive in soil free from lime. As a rule, the rooting medium is, to a certain extent, prepared for them by adding peat and leaf-mould in liberal quantities. A sunny position should be chosen. These plants can be increased by division and cuttings, methods recommended for choice forms; but if one is not particular in this direction, seeds offer a ready and interesting means of increasing the stock of these fine shrubs. Moreover, there is a possibility of raising improved varieties from seeds; but it ought also to be borne in mind that many will be inferior to those already in commerce.—T. W. B.

A Late-Flowering Rock Plant.

THE genus polygonum is a large one, but few are of any use for the rock garden, and, no doubt, the best of the family is P. vaccinifolium. Well grown examples are most effective in the early autumn, and it will continue to bloom for many weeks in spite of bad weather, which renders it a decided acquisition to the rock garden. Of neat trailing habit, it is a joy at all times, and, owing to its easy culture and rapid growth, it is an ideal subject for draping the largest rocks; in fact, few plants can equal it for this purpose. In such a position it can be viewed at its best, especially in the autumn, when the leaves and stems assume the most beautiful tints of red and crimson. It produces spikes of bright rose-coloured flowers, the tiny individual blossoms somewhat resembling the heaths in shape. When planted to cover a rock or bank, all the most desirable attributes of P. vaccinifolium are brought out, whereas on the flat ground they would be lost to a great extent.—B.



OF NEAT TRAILING HABIT AND WITH BRILLIANT AUTUMN COLOURING POLYGONUM VACCINIFOLIUM IS A DECIDED ACQUISITION TO ANY ROCK GARDEN.

Parker's Yarrow.

I SUPPOSE, by the rules adopted by those who prefer always to use "common" or popular names for plants, it is correct to write "Parker's Yarrow" for Achillea filipendulina Parker's variety; at any rate, it will serve the purpose of aiding me in emphasising the point that this is a very much finer plant than the ordinary Achillea filipendulina. There is a striking appearance of power in this plant as it holds up its solid-looking and somewhat massive flower-heads, defying wind, rains or scorching sun, and the strong pungent odour strengthens that first impression that here is a powerful plant.

There are those who believe that the odour of this achillea has disinfectant influence, and that infectious diseases are rendered less contagious where the atmosphere is laden with the aroma of the plant. If that is so it would be well worth while to plant great belts of it around isolation hospitals and sanatoriums, and even if there is more fancy than reality in the attribution of virtue to the plant, we have this much to the good—that auto-suggestion is itself a great factor in grappling with disease. Furthermore, we might plant many a worse subject on the broad open spaces which generally surround these frequently bleakly exposed institutions. Not many plants will endure such exposure with equal indifference, and it is when planted in bold masses that Parker's yarrow fully reveals its uncommon beauty.

It is a plant which pays for division every third year, and if it is mulched with manure during the spring preceding its autumn lifting and replanting there will be sufficient young surface roots to ensure successful transplanting.

Unlike many herbaceous plants, it is just as well to lift and transplant at the latter end of November or beginning of December (soil conditions being reasonably favourable) as to disturb in September or October, because development of new crowns is going on apace right through September, and lifting them puts a check upon that development.

The flowering period extends from early June to September, the quantity of late blooms being increased by cutting early flower stems low to ground.—A. B.

Oxalis for Growing Under Trees.

THERE is no more delightful oxalis for woodland than the bright rose pink form of our own wood-sorrel (Oxalis Acetosella), which will hold its own among such native herbage as the latter puts up with. This pretty little plant, one is glad to note, reproduces itself by seed and thus soon becomes naturalised, but it has not the sometimes aggressive vigour of the type. O. oregana is much like the rosy wood-sorrel, but at least twice as large in flower and leaf, a hardy, handsome and easy species. There are two forms of this American, with light and dark pink flowers respectively, and they will be in bloom for the greater part of the season.

O. obliqua, with its big, olive green, tin trefoils, each bearing broad crescents of purple, and tall flower stems terminating in cowslip-like heads of lilac, is another fine species for an open spot. Anywhere else this plant can be a dreadful pest, but it is well worth a place where it can do no harm, the foliage alone is distinctly attractive and it dies off a rich orange.

O. floribunda (rosea) is too much of a sun-lover for woodland culture, but its white variety is, oddly enough, very amenable to life in shade or partial sun. Nothing, not even drip, damps the cheerfulness of this useful little plant which, from spring to autumn, will maintain an unbroken succession of its ivory-white flowers.—A. T. J.

GARDENING WITHOUT A GARDENER

Hardy Ferns Indoors.

TOWARDS the end of the year it is worth while lifting a few clumps of hardy ferns and potting these up for growth indoors. Dig up the clumps with care, taking pains to disturb the roots as little as possible. Remove any fronds which may have remained over from the summer and put the ferns into pots filled with any common soil. Leave the crown of each clump quite clear of the soil, which should be rammed down well and not come to within 2ins. of the rim of the pot. For about a week keep the fern roots in a rather dark, cool place. Then bring them into the light and warmth of a living-room. Water should be given plentifully and the amount must be increased as soon as the fronds begin to come up. In a well warmed room the ferns grow with great rapidity, and it is not long before some very fine specimens will have been secured. The fronds are rather more delicate than those produced in the ordinary way and are always of a peculiarly vivid green. It is most important not to allow the ferns to become dry, and then they will remain fresh and beautiful for some weeks. Finally, the clumps may be returned to their original positions, when they will be found to be little the worse for their experience. Suitable subjects for this treatment are the common male and lady ferns and almost any of our native species.

Watch the Antirrhinums.

OLD plants of antirrhinum are well worth leaving in the border, as these will come into flower at an early date next season and maintain a wonderful profusion of bloom for a long time. They are perfectly hardy and are scarcely ever killed even by severe frost. Like most plants, they have a weak spot, and that is their extreme dislike to excessive dampness in the soil. Where the plants are growing in a light and well drained soil they carry through the winter well, even if the cold is severe. On heavy ground, after long spells of rain, antirrhinums often suffer badly, and it is not at all an uncommon thing for large numbers to die. In such situations it is really a good plan to lift the plants and place them in a cold frame where one is sure the drainage is good. Failing this, removal to some border with a south exposure where conditions will naturally be drier is to be recommended. Lift the plants with as little root disturbance as possible, and leave them in their new quarters until warm spring weather arrives.

Poppy Anemones in Winter.

ESTABLISHED poppy anemones, and even those which have been newly planted, have a habit of starting into vigorous leafage in mid-winter if the conditions are mild. Quite commonly, soon after the appearance of the leaves, flower buds begin to appear. Often the flowers open out, but, owing to the damage done by rain and wind, they are of little value. It is really worth while giving these venturesome blooms some protection, as then they will not be much inferior to those which are produced in the spring. The buds may be sheltered by means of hand lights, but it is better to use pieces of glass. Sheets of glass may be supported by four little stakes at the corners a few inches above the developing buds. In mild weather the anemones will benefit by the air which freely circulates under the glass. Should the conditions suddenly become cold and frosty, pack a little straw or any dry litter round the outer edge of the glass. In this way a miniature frame is formed in which the anemones will open perfectly.

When the Winter Jasmine is Most Effective.

THERE should be no garden without at least one plant of the winter jasmine (Jasminum nudiflorum). Even the worst of British weather seems unable to prevent this plant from displaying its bright yellow flowers. The winter jasmine is excellent for training up walls and fences, and, although it is happiest where the aspect is south or west, it will succeed quite well when facing the bleaker quarters. As the winter jasmine flowers before its foliage is developed, a much better effect is secured if the shoots are allowed to trail among ivy or some other evergreen foliage. Very pleasing effects can be secured by planting the jasmine in conjunction with ivy round an old tree stump, or, if this is not available, a framework of wire netting. In quite a short while the ivy entirely hides the support and during the winter provides a pleasant background for the flowering sprays of the jasmine.

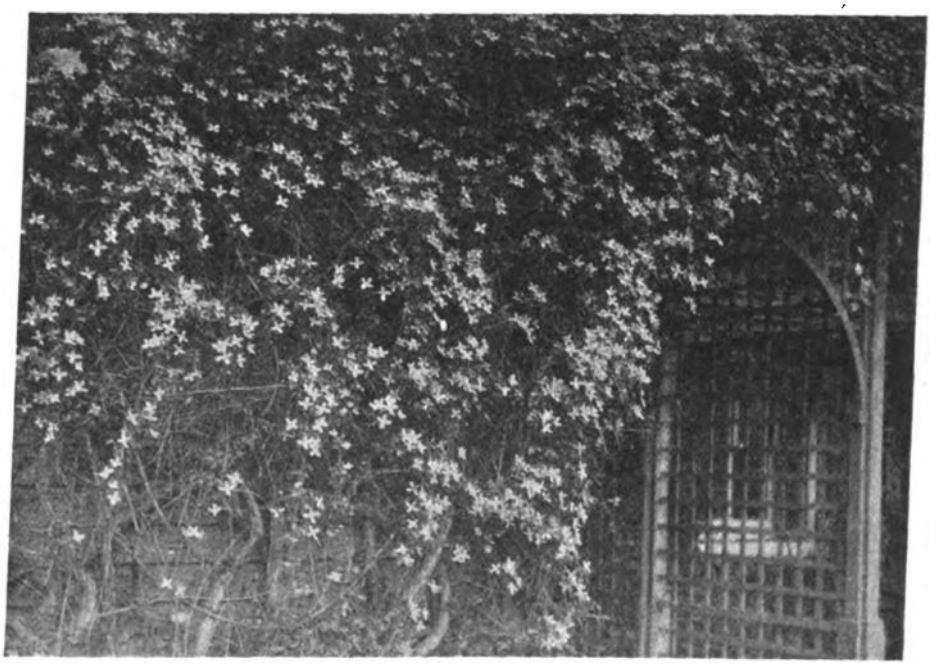
Fighting the Damp.

MANY perfectly hardy garden plants suffer badly from the excessive dampness which is often a feature of the British winter. The effect is specially noticeable in the case of those specimens which keep a certain amount of green foliage above ground, like foxgloves, campanulas, etc. Here, after weeks of rain, the foliage starts to rot and the trouble may end by spreading to the main stem of the plant and causing its death. It is a very good plan to examine such plants at intervals and carefully remove any foliage that has started to decay. Another step to be taken is an occasional light forking of the soil in the neighbourhood of the plants. This will allow a certain amount of air to pass into the soil and tend to reduce the excessive moisture.

Clematis montana.

A MOST useful and ornamental climber for late spring or early summer effect is Clematis montana. A plant, once established, will quickly cover a large area with a multitude of white starry blossoms each year. The mountain clematis loves to ramble over a wide and tall expanse of trellis, and makes a perfect bower when trained over a garden shelter or an archway above a seat. On the house wall (trained to trellis) and over the porch entrance it is equally beautiful.

Although vigorous, its habit is not too rampant, and it is easily kept within bounds by yearly pruning, which should take place after flowering is over towards the end of summer. When wanted to cover a large area quickly and permanently the main stems should be trained in and allowed to grow, only the laterals being cut back each year. This clematis gives little or no trouble, and could be grown in conjunction with a later-flowering climber to produce a long blossoming season. It is very welcome, however, in providing a show when few climbing plants are in bloom.



THERE IS NO MORE DECORATIVE PLANT FOR DRAPING A DOORWAY THAN CLEMATIS MONTANA.

A Shrub for Spring and Autumn Effect.

Amelanchier canadensis (*The Service Berry.*)

WHERE one has a limited space in the garden and cannot plant shrubs for autumn effect only, then the above shrub will prove most useful. Being a shrub of easy culture, preferring if anything a fairly dry spot, the lovely white flowers open early in April before its deep green leaves unfold. These are followed by crimson fruits, popularly known in Canada as service berries. The autumn colouring of this shrub is a very attractive red, the leaves lasting on the trees long into the autumn. No doubt in the Midlands and the North it would require a sheltered position on account of its early flowers.

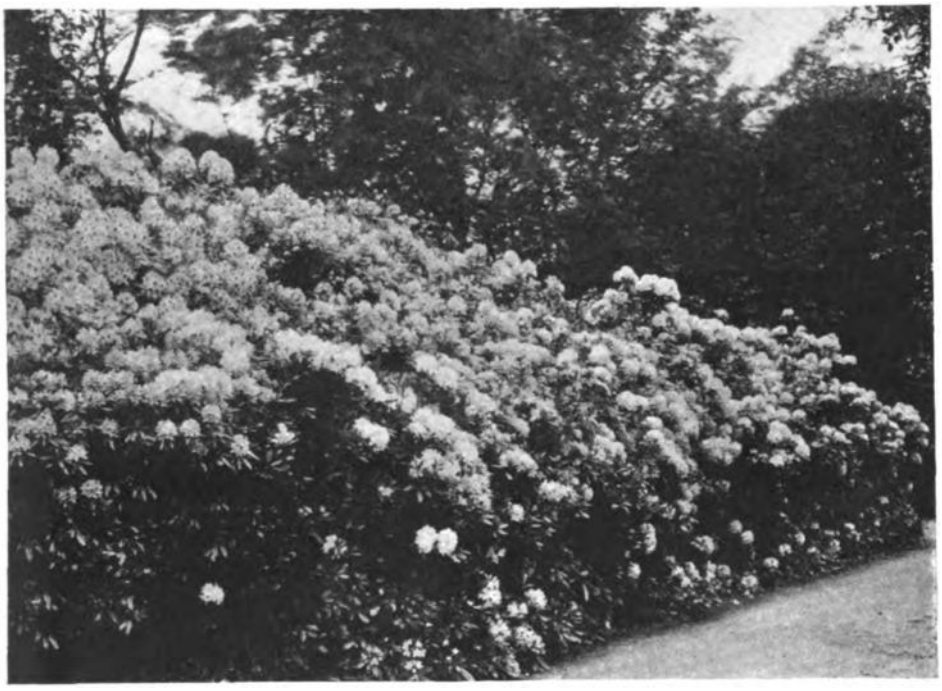
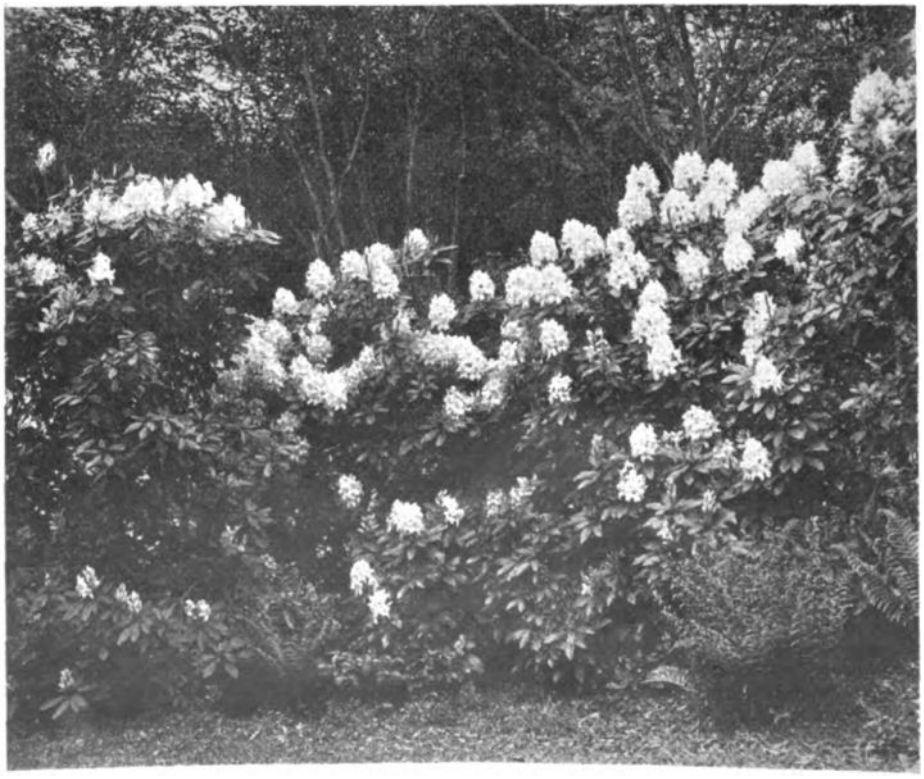
SUCCESS WITH RHODODENDRONS

WHATEVER class of rhododendron is grown, its ultimate success as a flowering shrub depends on two main factors—its situation and care in planting. Popular though these magnificent flowering shrubs are, they would become still more so if gardeners would only realise that, while the majority of hybrids and many species are absolutely hardy, the difference between a bushy healthy plant and a struggling tattered shrub is usually caused by the poor selection of site for the latter and insufficient care in planting. Many rhododendron hybrids have no objection to sun, but all rhododendrons, no matter what species or variety, dislike wind. Let us classify what they prefer in the way of situation.



A FINE BANK OF OLD RHODODENDRON HYBRIDS GROWING IN NEARLY FULL SUN.



GEORGE HARDY IS AN EXCELLENT HYBRID THAT OPENS PALE PINK AND TURNS TO ALMOST PURE WHITE.

1. SHELTER FROM WIND.—A necessity for all rhododendrons.
2. SUNSHINE.—(*a*) Full sunshine will do no harm to most of what are called hardy hybrids, such plants as Pink Pearl, Cynthia, Cunningham's White and so on, though it must be realised that even these will produce larger foliage and flowers if they are shaded for an hour or two from the midday sun.
   (*b*) Half sunshine for most species and for the more aristocratic hybrids such as Loder's White and Mangles.
   (*c*) Well shaded, at the most two hours sunshine in summer for big-leaved rhododendrons such as Falconeri.
3. SOIL.—All gardeners know that absence of lime is a necessity. It is stated occasionally that some rhododendrons will grow in lime, but they are never really satisfactory. So many other shrubs will succeed admirably that it is a waste of time to try to grow rhododendrons. They will grow in all lime-free soils. If it is on the heavy side the soil should be lightened by sand, gravel and humus either in the form of peat or leaf-mould. In all cases the drainage must be good.
4. EXPOSURE.—It is better to grow rhododendrons where they are sheltered from the early morning sun, as flower buds are most likely to be cut in frosty mornings in spring if they are exposed to the sun before the frost has lifted. A westerly exposure is best of all.

If you keep these few hints in mind, most rhododendrons that are suitable for an ordinary garden will not grumble at the situations you choose for them.

Planting.

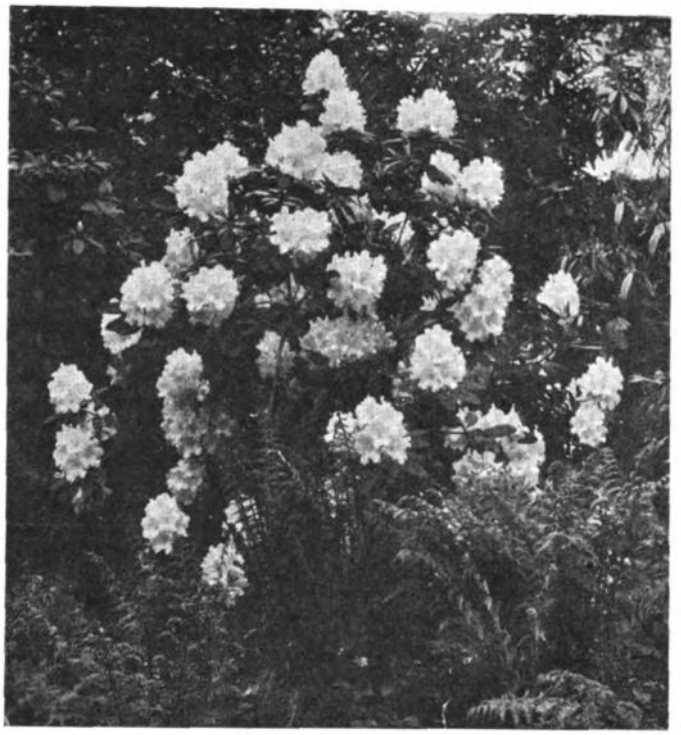
It must be remembered that rhododendrons are shallow rooters. The roots are fibrous and reach up towards the surface of the soil for moisture and nourishment, which means that they should not be planted too deeply, a very common error which is not conducive to the formation of good plants. A hole at least a yard in diameter and 18ins. deep should be dug and the soil loosened with a fork below that. A good proportion of humus is a necessity for their well-being, so soil and leaf-mould mixed in equal proportions should be used to fill up the hole again so that the depth is not too great and the roots are not too deep in the ground. The soil need not be trodden in. Before the plant is placed in position, it should be turned over and the fibrous roots loosened and teased out and old soil removed; this means that fresh roots will be formed quickly, an important point. When the plant is in position the roots should be spread out and just covered with more soil and leaf-mould, which then can be firmly trodden in. This should result in a saucer-shaped depression being left around the plant, which will be found most useful for the annual spring mulch of old leaves, coarse leaf-mould or peat moss litter, which is strewn lightly around the plant. This mulch is not only an excellent feeding and rooting medium, but keeps the soil by the roots cool and moist during even the driest weather. This annual mulch, indeed, is a necessity in all cases, and will improve the plants enormously. The reason for the stress being laid on the use of humus is that rhododendrons are starved in many gardens. In their native habitat they live

Digitized by Google

in soil that is almost entirely composed of leaf-mould or peat, and it is just this humus that is so often denied them.

Twelve Good Hybrids for the Small Garden.

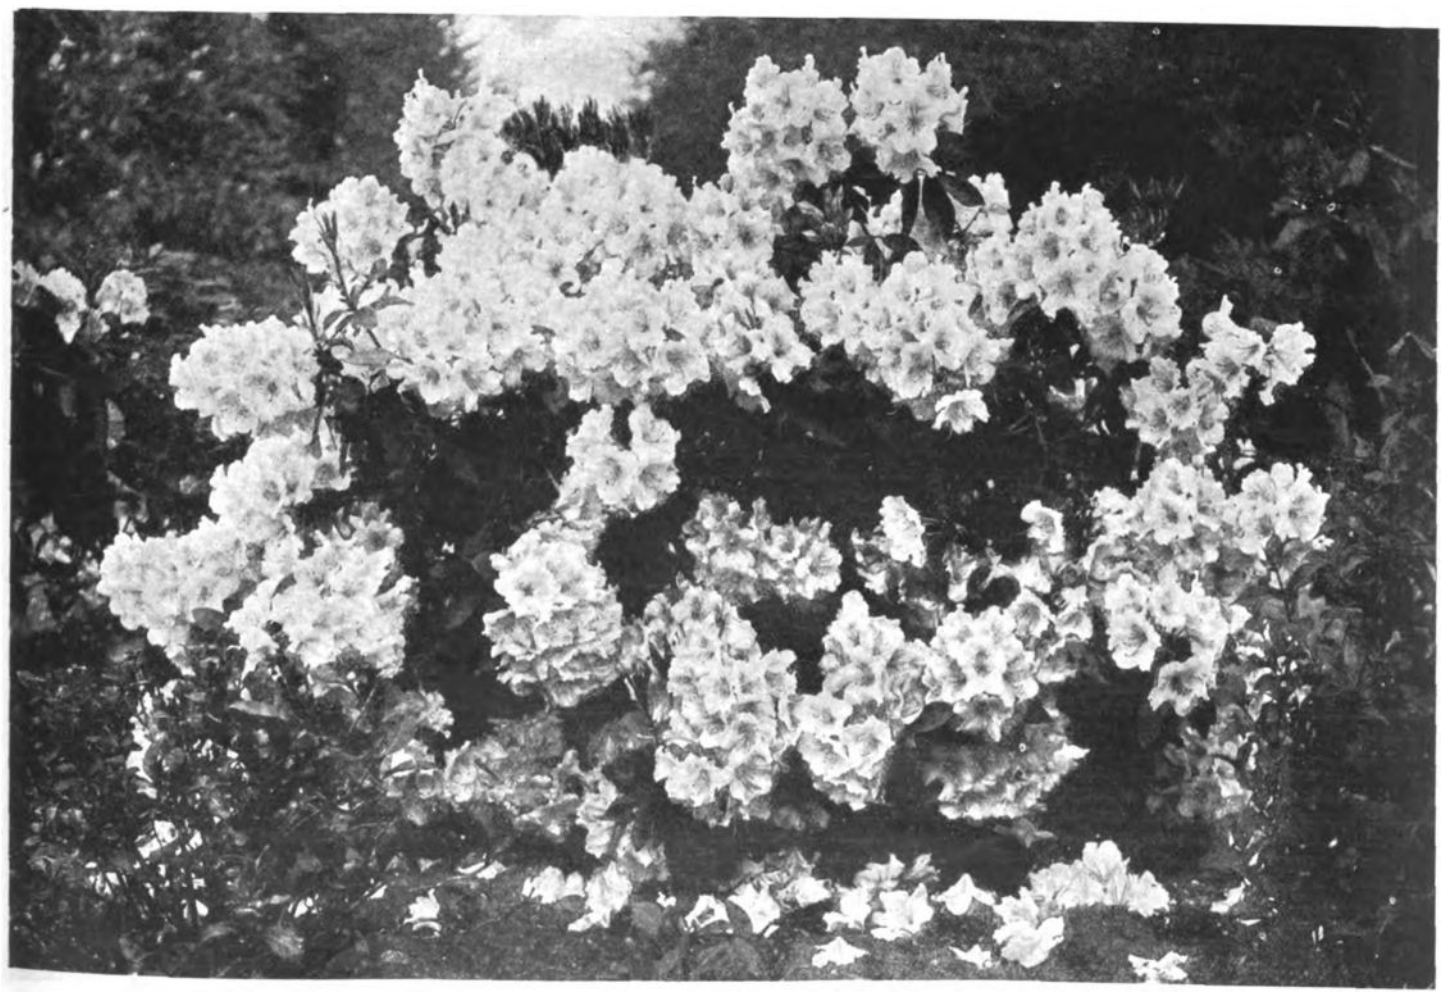
The small garden can rarely give situations suitable for many of the rhododendron species, and for the more tender hybrids that must have shade and shelter. On the other hand, hybrids of strong constitution exist in sufficient quantities for ample choice to be made. It must be remembered that when rhododendrons are well grown, they take up a considerable amount of room, and that ample space is necessary for them to flower abundantly and for their beauty to be fully seen. They are, however, easily transplanted, and so one plant can be removed out of a clump to allow for the expansion of others. Here are twelve good hybrids that are suitable for all gardens, large or small. Most popular of all is Pink Pearl, and rightly so, for its constitution, colour and free flowering habit are all admirable qualities. It flowers in May and bears large trusses of a fine pink. Almost as good, with trusses as large as the latter, is Alice, but the colour is deeper. The third pink that should be grown is Corona. In this the buds are deep rose, and as the flower ages every shade of pink is shown. These three plants can be grown together without any clashing of colour.



ALTHOUGH EXOTIC LOOKING THIS LOVELY HYBRID, LODER'S WHITE, IS ABSOLUTELY HARDY.

Of reds one of the best is a comparatively new variety, the Earl of Athlone. The trusses are large and are of an intense shade of blood crimson. It is exceedingly free flowering in May, year after year, and flowers when quite young. Other good reds are Bagshot Ruby, which is well named and flowers in May; Doncaster, a bright red, in May and June; and Ascot Brilliant, a red-crimson, and rather earlier in flower, usually in April. In whites we find Loder's White, one of the best of all hardy hybrids with enormous trusses of the purest white. It is the largest flowered rhododendron for ordinary gardens. George Hardy opens pale pink and turns almost pure white as the flowers grow older. As a purple you cannot better Royal Purple, a very deep and pure shade; while for a yellow there is Cunningham's Sulphur, a pale lemon and not a fast grower, but very free flowering and charming.

E. H. M. Cox.



PINK PEARL IS ONE OF THE MOST POPULAR OF ALL RHODODENDRONS. IT IS A GOOD GROWER, VERY FLORIFEROUS AND OF A WONDERFUL COLOUR.

THE FRUIT AND KITCHEN GARDEN

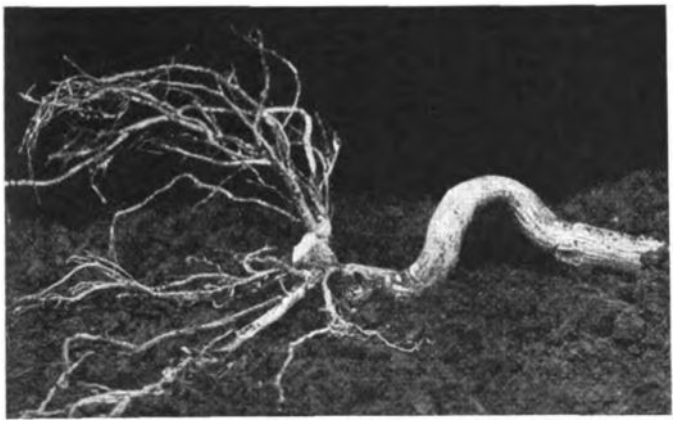
Root Pruning.

THIS is a strenuous operation that no one wants to undertake unless assured of beneficial results; therefore it is best to be quite certain that root-pruning is really needed before attempting to mutilate a flourishing root system. If the tree is bearing well, let it alone.

Some trees, however, require systematic root-pruning. A tree of any sort, planted on a rich subsoil or one that is very retentive of moisture, such as clay, is encouraged to send long, thick roots downwards to a great depth; this induces growth of a mass of shoots and leafage to the detriment of fruit production. The tree flourishes and expands, but bears little fruit.

Its activities must be checked. It is of little or no use to prune the branches or shoots, for the vigorous tree promptly repairs the damage by producing a greater number of thickly placed shoots, thus leaving matters worse than before the pruning took place.

A more severe check must be given, and this is best accomplished by attacking the thick roots. It is well to note that as soon as a root is severed in two, like the branch above, it immediately sets to work to repair the damage; but in this case it is a beneficial action, because around the cut part a mass of fibrous roots is formed, and these, being necessarily near the surface, receive light, air and equable moisture which induce fruit formation instead of rank growth. Moreover, these roots can be artificially fed by the fruit-grower, which is an advantage in the way of stimulating fruit production. It will be readily understood that this cannot be the case with the long thick root deeply embedded in the subsoil.



A MASS OF FIBROUS ROOTS ARE FORMED ROUND THE CUT PORTION OF THE THICKENED ROOT.
These add considerably to the fruitfulness of the tree.

It is well, then, to take in hand a rank-growing tree that persistently produces shoot and leaf instead of fruit; and, in order not to put too great a check upon the tree, it is advisable to treat one half of the roots one year and the remainder the next season.

Take out a deep trench a couple of feet wide around the tree on one side. Dig carefully, and do not injure any *fibrous* roots. When a stout root that *has a downward tendency* is laid bare, saw it in two about a foot from the trunk of the tree. It is not necessary to remove the cut portion of the root, but if it is easily drawn out or a portion cut off, so much the better. Serve similar roots in the same manner, and replace the soil, or put a richer, leafy, sandy soil in its place. Fibrous roots will soon form, and if these are judiciously fed from time to time, an appreciable difference in the way of increased fruit production will be the result. Pears, figs, peaches and vigorous kinds of apples are often in need of root-pruning, wall trees and standards especially.—H. A. D.

Best Apricots.

SOIL well dressed with chalk will be found most genial to the well-being of the apricot, arresting the too prevalent annoyance of persistently dying branches. Oxfordshire appears to give better results from apricot growing than most other counties.

Large Early.—Fruit medium size, skin pale orange on the shaded side, bright orange and spotted red next the sun, slightly downy. Flesh deep orange, rich, juicy, free stone, ripening end of July and beginning of August. Introduced to commerce about 1875.

Moor Park.—A best-of-all variety and known since the seventeenth century. Fruit large, roundish and compressed on the sides, giving the fruit an irregular form. Skin pale yellow on the shaded side and deep orange, clouded with brownish red next to the sun. Flesh deep reddish orange, very juicy, rich and vinous, free stone. A fruit of great excellence, ripening in August and beginning of September. A south-east aspect is the best for this apricot, firm planting and attention to the pinching of surplus growth during the summer. Mention of this variety was made about the year 1784, and is still very much in favour.

Shipley.—A very free setting sort and perfectly hardy, raised at Blenheim about the middle of last century. Fruit large, oval, skin deep yellow. Flesh yellow, rich and juicy. Ripe end of July, making excellent preserves.

Hemskerk.—Large, early, with a greengage flavour, round, flattened on the sides. Skin yellow on the shaded side and reddish next the sun. Flesh bright orange, tender, rich, and juicy, ripening beginning of August. The tree is hardy and very prolific and not so liable to gum and die off in a manner so prevalent among the apricot family.—G. L.

The Loganberry.

THIS is not a difficult fruit to grow where there is ample space for the extension of the branches. It is not a suitable plant for a very small garden unless the rambling shoots can be trained over a trellis so that they will form a much-needed screen during the summer months. It is the result of a cross between the raspberry and blackberry and is nicely flavoured when the fruits are ripened in a sunny position. They are not appreciated by everybody as a dessert, but are useful for jam making. The soft or immature tips should be pinched or cut off now and the old canes shortened in the case of newly-planted specimens. Older established plants should be treated just the same as raspberries. The loganberry is a gross feeder and soon extracts practically all nourishment from the soil. Those contemplating the planting of young specimens should take some extra care in the preparation of the soil, trenching it 2ft. deep and enriching the top portion with well rotted manure and, after the work of planting is finished, top-dress with a layer of littery manure 4ins. thick. To increase the stock, suckers, similar to those of the raspberry, or layering of the tips of longer shoots, will answer the purpose. In large gardens long rows of plants may be trained to poles, tall stakes or wires fixed to strong stakes. To avoid unpleasantness with the plant, good training is advised and the present is a suitable time to arrange the main shoots to their supports.—G. G.

Making Potatoes and Roots Secure for the Winter.

THESE are, mostly, now in store, either in clamps or in sheds. But very often the cultivator does not pay enough attention to the covering material. In mild winters it is only necessary to put on thin layers, but if hard weather comes, we should be prepared. Throughout the country, headlands, hedges and banks have been trimmed recently and, although the trimmings may consist of small brambles, coarse grasses and creeping weed foliage, all should be heaped and kept dry in readiness for placing over potato and root clamps in the open air if severe frosts come. It is really wonderful how well the dried rubbish acts as a frost excluder, especially when it is kept dry. Indoors, straw and short litter can be used and there should always be a good thickness of such material between the potatoes and outside walls.

Many amateurs do not possess any straw, nor are they able to procure it for storing their beet and carrots. To meet such cases, store up the dry ashes and mix them with dry sand or dust-dry garden soil and pack the roots in the mixture. So treated the roots will be quite safe from moderately severe frosts, and, in case of prolonged frosts, more dust-dry soil can be heaped on. It is very important that the material be kept dry.—HANTS.

Hotbeds from Leaves.

IT is a mistake to suppose that stable litter is absolutely essential for the making of a hotbed. Quite a good bed can be formed from leaves alone, and although the heat will not be so great as that produced by manure, yet it will have considerable lasting properties. If a variety of leaves can be secured so much the better, for the different sorts vary somewhat in the time taken to start fermentation. Thus the giving out of a mild heat is extended over a considerable period.

Much depends on preparing the heap of leaves for the hotbed. Heap the leaves up in some odd corner and turn and shake the pile about every other day for a week or a little longer. If any part seems at all dry water should be given freely. At the end of the period named the material will be ready for the making of the hotbed. The leaves may be placed inside any permanent pit which has been opened out to the depth of at least 2ft. 6ins. Where the hotbed is to be made on the surface of the ground the thickness of the layer must be from 3ft. to 4ft. apart from the necessary filling of the frame. The leaves should also extend for a distance of 3ft. on all sides of the frame. It is most important that the whole mass should be firmly and evenly trodden to secure against any one part settling together closer than another and for securing a uniform heat throughout.

Even a hotbed made of leaves should not be used straight away. During the first three days allow rather a free ventilation, at the end of which time the bed will be ready for use. Where it is desired to propagate cuttings or seeds a layer of soil from 6ins. to 9ins. deep may be spread on the surface of the leaves. Pots with plants may be plunged right into the bed.

Digitized by Google

THE WINTER SPRAYING OF FRUIT TREES

An important operation which should be carried out during the next few weeks.

THE spraying of fruit trees is an operation which is often neglected by the amateur. That it is important really goes without saying, when one thinks of the multitudes of insect pests and fungus diseases which attack our trees and injure them in some way, either by disfiguring or ruining the fruits, eating the leaves, which are the actual food manufacturers of the plant, or crippling the shoots.

There is no comparison between a tree which is allowed to care for itself and a tree which is properly sprayed and pruned. The one may give us a good crop of usable fruit occasionally, while the other will give us good crops of first quality almost every year.

At present I intend to deal only with spraying fluids for use during the dormant season, when, of course, we are able to use much more powerful solutions than is possible when the foliage is on the trees.

The first consideration is to cleanse the trees from the covering of moss and lichen which is to be found on the stems and which harbours so many insect pests and their eggs.

One of the best cleansing washes we have, and certainly the most simple one to mix, is a plain *Caustic Soda Wash*. This is prepared by dissolving one or two pounds of caustic soda in ten gallons of water. This is a powerful solution and as it has strong caustic properties, care must be exercised in using it. Rubber gloves should be worn and the face smeared with vaseline. Old clothes should, of course, be worn. When young trees are being sprayed, one pound of caustic soda in ten gallons of water will be strong enough and it is advisable only to use the 2 per cent. solution on old trees.

Strong Paraffin Emulsion is used during the winter when apple scale is troublesome. This wash also has some effect on insect's eggs, but is not entirely satisfactory as an egg-destroying wash. This mixture is made by boiling one to two pounds of soft soap in a gallon or so of water and stirring in one gallon of paraffin while the solution is boiling. If stirred briskly for a while the paraffin will emulsify in the boiling soap solution. This strong solution should be made up to eleven gallons with water before use.

Where it can be obtained, soft water, rather than hard water, will be found much better for the mixing of these washes, in that it ensures a more efficacious spray.

Lime-Sulphur is another substance which is recommended for winter spraying, especially when fungus diseases prove troublesome. Being a difficult compound to make up satisfactorily, it is advisable to buy the ready-made proprietary article. Firms which manufacture large quantities of this compound have greater opportunities of preparing properly made lime-sulphur than has the man who only makes up a gallon or so in his garden.

The Tar Oil Washes.—The carbolineum or tar oil sprays form a new class of winter washes which will be found most effective. The first of these was introduced to this country five or six years ago. Since then many English insecticide manufacturers have placed brands of tar oil emulsions on the market. Several good makes are advertised in THE GARDEN. During the last three or four years extensive trials of these "carbolineum" washes have been made and from my own observations I can safely say that this type of wash is far before anything we previously had.

As far as cleansing the bark is concerned, these washes are as effective as caustic soda and they are a decided advance when we consider their action on insect pests. By systematic and regular spraying all the insect and fungus pests found in the trees will be destroyed in a short time.

This class of wash does not seem to injure the face and hands, but at the same time it should not be allowed to touch the skin if it can be avoided. A good plan is to wear goggles and to put some vaseline on the face to ensure perfect protection.

I must just add a word of warning regarding the use of carbolineum spray fluids. Use them as early in the new year as possible, in any case no later than February, otherwise the buds of the trees may drop. N. D. H.

WHAT OUR READERS SAY

AN ORNAMENTAL GRASS.

SIR,—I first saw that ornamental grass Spartina cynosuroides growing in Mr. G. H. Dalrymple's nursery at Bartley. I have not seen it anywhere else or in any catalogue. It grows to 6ft. high, broad, arching, emerald green foliage, edged with yellow. In August the flower-heads appear. It is a most attractive variety and ought to be seen more often. I have a large bed in my water garden and this autumn it turned a most lovely golden colour, and after all these heavy rains it is quite as beautiful to-day (November 16th). I think it likes a fairly moist soil, but seems happy anywhere.—MARQUE THURSBY, *New Forest*.

AMARYLLIS BELLADONNA.

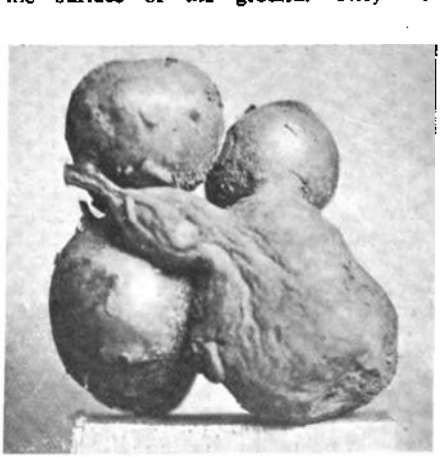
SIR,—The experiences of Mr. Woodall and Mr. Wood with Amaryllis Belladonna this season are most interesting to me. With us here I have never seen such a wonderful show of bloom. In a batch of 2yds. square I counted seventy spikes, some of them 3ft. in length, and very strong and fully developed. They have never flowered the like before. In some seasons I have had but just one or two spikes, and those very poor. Nothing was done to the bed other than a light top-dressing of soil. A row running at the foot of a south wall also flowered profusely only planted three years ago.—J. S. HIGGINS, *Llanwnda, Carnarvon*.

A SLUG COLLECTION.

SIR,—Referring to Mr. Williams' account in your issue of November 20th, I am tempted to send you my record over a similar period. My garden has a clay subsoil and nearly three-quarters of an acre in extent, and must have been greatly neglected in the past, as an entirely new herbaceous border of 120ft. was almost completely eaten up by the early spring. By means of orange and grape fruit skins placed along the borders and beds I collected 41,049. The skins were examined each morning before 6 a.m. and again after sunset. I can strongly recommend this method of collection to those who do not mind the hand-picking remedy.—CHAS. F. FAULKNER, *Cheshire*.

A POTATO FREAK.

SIR,—The accompanying illustration of a curiosity in potatoes may be of interest to readers of THE GARDEN. The potatoes were of the Epicure variety, and grew on the surface of the ground. They were



A POTATO CURIOSITY.

discovered among the dead leaves of a potato plant when the crop was dug. I should like to add that these potatoes were photographed just as they grew, and not joined by any artificial means. The matchbox they are placed on happened to be the most convenient thing handy, and one pin was used to secure them in position.—E. F. LAWRENCE, *Hamble*.

FIRST-CLASS DESSERT APPLES.

SIR,—Those who appreciate a first-class dessert apple would undoubtedly put Cox's Orange Pippin at the head of the list. I have always thought Cox's Orange the only apple worth eating and that it takes a lot of beating. I recently had the opportunity of tasting Laxton's Superb. It is well named, for the flavour is equal to Cox's Orange. The raisers, Messrs. Laxton, state that it follows Cox's Orange, but the fruit I ate was straight off the tree on November 1st and it was quite ripe, but no doubt the district and season would account for this. Given all things equal, I dare say Cox's Orange would hold its own, but as it is selfsterile and liable to disease, it is not everybody who can grow it, nor will it grow anywhere. Superb, being self fertile, and free from those diseases that Cox's Orange is liable to, should enable and encourage everyone to grow it. The trees I saw were growing beside the same number of Cox's Orange of the same age and planted at the same time. The Superb each carried a good crop of fruit. The Cox's Orange did not carry a single fruit. I write merely as an apple eater and not as a fruit expert. And to those who appreciate Cox's Orange and cannot grow it, I suggest trying Laxton's Superb. I don't think they will be disappointed.—POMME.

THE SIBERIAN PEA-TREE.

SIR,—Although one rarely sees this shrub, Caragana arborescens, planted to any great degree, it has much to commend it. Firstly, for its hardiness it is useful for exposed positions; secondly, its yellow pea-shaped flowers, which are borne in profusion in May, continue for a long period; thirdly, its quick growing and responsiveness to hard pruning. It seems to thrive anywhere

Digitized by Google

in well drained soil, and is easily propagated by seed.

C. pygmæa, another species is only 1ft. in height and makes a good shrub for the rock garden. In Canada Caragana arborescens is used extensively as a hedge plant, and seemed very useful in this way. The caragana comes from parts of Asia.—R. MOORE, *Thorpe Hall, Essex.*

AN APPRECIATION.

SIR,—Not only the chrysanthemum and dahlia world, but also all those interested in general horticulture, will feel the tragic death of Mr. Harry Woolman, of the Sandy Hill Nurseries, Shirley, Birmingham, which occurred in the disastrous railway accident at Rotherham. Many striking tributes have already been paid by those associated with him. As an amateur I should like to add my appreciation of his work. During his life, while engaged, along with his brother, in the business established by his father, he did much to popularise the chrysanthemum and dahlia and to bring them within the scope of the ordinary amateur's garden. He gave to our gardens many excellent varieties which will long remain among the best garden sorts and only this year he gained numerous awards at various autumn flower shows for new varieties he was exhibiting for the first time. He was always interested in the problems of the amateur relating to the culture of his favourite flowers and always eager to give freely of his help and guidance out of the vast store of practical knowledge which he had gained during his life.

His interests were catholic and he took an active part in many horticultural societies and in this way greatly strengthened and furthered the cause of flower growing in this country. Lovers of chrysanthemums and dahlias have not only lost a friend, but also a helpful and guiding colleague.—T.

[We have been asked to insert the following letter of thanks from Messrs. H. and J. Woolman: "Mr. H. Woolman sen. and Mr. J. Woolman take this opportunity of thanking all kind friends and customers for their many expressions of sympathy in the tragic loss of Mr. Harry Woolman as a result of the terrible railway accident at Rotherham. They feel that a deep debt of gratitude is owing to all for their kind expressions and floral tributes, and would ask all to accept this intimation of their sincere thanks. The business will be carried on as before by Mr. H. Woolman sen. and Mr. J. Woolman."—ED.]

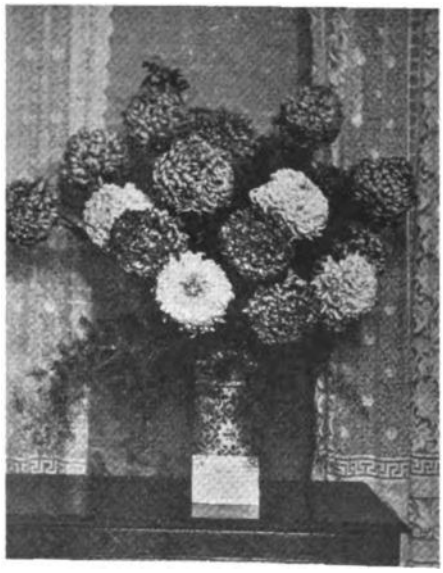
EARLY-FLOWERING CHRYSANTHEMUMS.

SIR,—The select list of early-flowering chrysanthemums given on page 662 of your issue of November 20th is very interesting. I have grown, in the neighbourhood of London, practically all the varieties you mention; but I would recommend, above, all a variety you do not mention—the deep maroon Wembley. The plant is very vigorous, the blooms are large and freely produced and the flowering period is exceptionally long. Although my cuttings were not planted out until the 20th of May, I picked the first bloom of Wembley about the end of August and the last on November 18th. September Glory, Mrs. Jack Pearson, Bronze Early Buttercup, Dick Barnes and Phœnix have also done very well indeed and bloomed continuously for about the same period as Wembley. Phœnix is a fine variety, though with me the later blooms have been very much smaller than the early ones. The other varieties mentioned have maintained their size throughout. I think that THE GARDEN has recently improved almost beyond recognition, and I recommend it to my friends with real enthusiasm.—E. T. THISTLETHWAITE, *Barnet.*

PRIZE-WINNING CHRYSANTHEMUMS.

SIR,—I am enclosing two illustrations of a vase of chrysanthemums which may be of interest to your many readers of THE GARDEN. Both vases were awarded first prizes at the National Chrysanthemum Society's recent show. The vase of Japanese varieties include the following sorts, W. Rigby, Mrs. Drabble, Queen Mary and H. E. Converse, of which the largest specimen measures nearly 11ins. across; and the singles are Sweet Auburn,

A PRIZE WINNING VASE OF SINGLE CHRYSANTHEMUMS.



A WELL ARRANGED VASE OF THE MOP-HEADED JAPANESE VARIETIES.

Glorious, Bertha Fairs, Mrs. Loo Thomson. Both vases were grown by G. Richardson, Tulse Hill, London.—F. J. HEATH, *Brixton Hill.*

THE CULTIVATION OF A SMALL GARDEN.

SIR,—On light, easy-working soil in Oxfordshire I found 20 rods not too heavy a task to cultivate after leaving my regular employment at 5 p.m. (Saturday afternoons at 1 o'clock). I grew potatoes early and late, and produced about 6cwt. to 8cwt. for use; onions, carrots, beet, parsnips six rows of each across the piece of land, which were sufficient for our use. I manured for potatoes and followed with greens, peas four rows across, also gooseberries, currants, raspberries, loganberries twelve trees of each; celery usually one row and such crops between as marrows, lettuce, etc. At the end I always had the children's garden, about 20ft. by 18ft. On this we grew sufficient flowers to keep us going and at the same time giving great pleasure to the children. Winter greens followed early potatoes, dug first week in July. This provided us with garden produce for ten months of the year.

On coming to Essex clay soil I found a great difference. Ten to fifteen rods were sufficient to undertake, that is, ten for allotment such as above, and five rods of such flowers as roses, carnations, sweet peas, phlox, etc., with annuals between and a piece of grass 30ft. by 40ft. This, I find, employs me on the average two hours per night with an occasional Saturday afternoon from April to October. A plan which will be found to save much time and labour in small gardens is that of ridging up all vacant land after removal of crops as recommended in a recent issue of THE GARDEN. This is the secret of a good start in spring.—H. M. BUTLER, *Woodford Bridge, Essex.*

SIR,—In answer to the enquiry in THE GARDEN for November 20th, *re* the amount of ground that can be cultivated, I have an allotment of 10 rods which I cultivate year in and year out. The ground is rather on the heavy side, as it is close to a river, which supplies a ditch that runs parallel with my ground. A twentieth part I use for perennials, and the rest for annuals and vegetables. During the winter months I turn over the whole of my ground, working Saturday afternoons only. When light evenings are here I utilise four or five for the garden, and I can safely say that I have no weeds growing, although the adjoining allotments are, in some cases, overgrown with them. My success in keeping weeds down is due to using the hoe freely. There have been occasions when I have made work, there being nothing really necessary to do. Besides the allotment I have a very large aviary of foreign birds to care for at my home. I think, myself, that 12 rods can be cultivated with ease providing that the soil is not composed of too much clay. If the soil consists principally of clay, then 6 to 8 rods is quite sufficient —F. J. STEVENS, *Lower Tooting.*

THE IMPORTANCE OF LABELLING.

SIR,—With reference to the article on "The Importance of Labelling" in the issue of THE GARDEN for November 13th, the paragraph referring to the oxidising of zinc labels I consider misleading to those uninitiated, and I think should be corrected. The paragraph I refer to reads as follows "and the old-fashioned zinc label which has the disadvantage of oxidising and becoming almost unreadable in time." Later in the same paragraph reference is made to cast labels being the most permanent. I do not know of any cast garden label that is not made of zinc. In addition our Acme label is made of stamped zinc. My point is that anyone reading your article on labels and reading your paragraph *re* the oxidising of zinc, would naturally infer from it that all zinc labels become oxidised and illegible, and would therefore refrain from buying cast zinc labels. You are correct in stating that zinc oxidises when exposed to the weather. Everything is affected in time in one way or another by exposure to weather, but it is the fact of there being raised letters to our labels (both cast and stamped) that ensures their legibility for all time.—TRISTAN PINCHES.

[Through inadvertance it might be supposed in the note refered to that cast zinc labels oxidised in the same way as the old zinc labels which were written on in ink. This is not the case.—ED.]

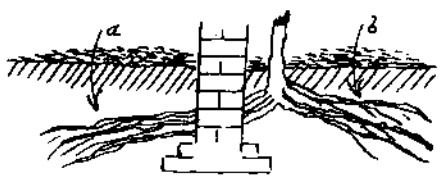
IN THE GREENHOUSE

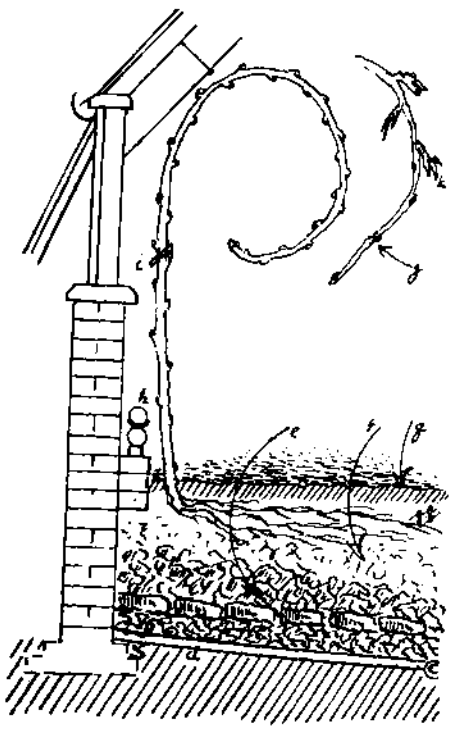
Present Treatment of Pot-Grown Strawberries.

AMATEUR cultivators like growing strawberries in pots and even a few dozen plants will yield several dishes of very fine fruits if they are well managed. Usually, the pots are taken straight to the greenhouse shelves, which are dry and near the roof glass. In such positions, at this time of the year, new roots are slow in growth and it is important that they be active when the crowns of the plants begin to grow. Take the plants to a frame first and plunge the pots to their rims in a mild hot-bed. In a fortnight new roots will have grown about half an inch long; then place the pots on the surface of the bed for three days before taking them to the greenhouse. At intervals of ten days, or so, plunge pots in the hot-bed and, in this way, maintain a succession of ripe berries until the outdoor ones are available. This is a better plan than having all the berries under glass ripening at the same time. Only use clear water until the berries have formed then begin to feed with weak doses of liquid manure and concentrated foods.

Planting Young Vines.

THE accompanying sketch shows how a new border should be constructed and young vines planted. It is never advisable to have the bottom of a border below the wall foundations; rather build up somewhat above the normal level of the ground, having the border partly below and partly above the ground level, except in cases where there is a border outside the vinery as well as inside the house, as shown at *a* and *b* in the diagram. If convenient, put down a cement base, shown at *d*, and in a slightly





inclined plane, so that all surplus water will be conveyed away by drain laid at *c*. On a rubble base lay whole turves, *e*, grass side downwards, then the main bulk of the compost, *f*, on which the roots are neatly spread out and covered with 4ins. of soil, as shown at *g*. A few bricks, laid in cement, will support the pipes shown at *h*, the heat from them warming the cold air as it enters the house before it reaches the tender foliage. If the young cane is cut back before the second week in January there will not be much danger of loss of sap from bleeding. It should be cut off at the point *i*. If pruning back cannot be done by the time named, then it is best to depress the young vine as shown, and when the buds begin to grow to rub them off while very small down to the point *i*. At *j* the method of disbudding a young vine is shown. The denuded portion of the young rod can be cut away at midsummer or the following autumn.—G. G.

Forcing Mint.

FRESH mint is appreciated in every household. There is no difficulty in obtaining nice green leaves where greenhouses or frames are available. The new shoots must be obtained from divided roots or, more correctly, runners which resemble those of the objectionable couch grass. Mint luxuriates in a moist soil and where a little aritficial heat can be used very quick growth results. A bed of soil about 9ins. deep is better than a box or a pot, but failing a bed, make use of boxes at least 7ins. deep or pots 9ins. across. Use a rich compost; rotted manure in the bottom of the pot, box or bed and also rotted manure, burnt soil and a few wood ashes mixed with the general compost. A rather heavy loam is better than a light, sandy one. Firm the compost by hard pressing down with the fingers; lift old roots, disentangle them and lay in the strongest, quite flat, 1in. apart, covering with 2ins. of soil. One thorough watering should be given directly the planting is finished and afterwards the soil must be kept in a consistent state of moisture. If the roots of mint are allowed to get very dry the stems become wiry, hard and the leaves small and subject to red spider attack.

Peaches and Nectarines.

THE trees growing under glass should be cleaned and the branches and shoots tied to the wires by the end of December. It is never safe to meddle much with the branches in the way of cleaning after mid-January, as the sap begins to move and the buds to swell at an early date. If possible, the structure in which the tree or trees grow should be ventilated to the full and this can be readily done if the trees are the sole occupants. In calm weather, frosty or not, open ventilators and doors wide. After the structure and the trees have been cleaned, tie the main branches out, evenly, first; then the young shoots not closer together than 4ins., 6ins. would be better. The last work to attend to will be the application of rotted manure, old mortar rubble and fibrous turf, chopped, as a top-dressing 3ins. deep, and a final watering, making sure that the soil in the bed is thoroughly moistened down beyond the point where the roots go.

Propagating Chrysanthemums.

CULTIVATORS wish to avoid spoiling their plants and to grow strong specimens—such that will bear, in due course, fine large blooms of great depth and solidity for exhibition or sturdy specimens that will bear from nine to thirty medium-sized flowers for purely decorative purposes. Both are obtained by growing the plants from the cutting to the blooming stage without unduly subjecting them to a strong heat or a too confined atmosphere. The chrysanthemum is a cool temperature plant.

By this is meant that it thrives in frosty weather, there is no ordinary plant that does, but frost will not kill it, although severe weather stops, or retards at least, the growth. So we must, while not coddling the plant, keep it free from actual frost in the propagating house. We should be busy now preparing and inserting the bulk of the cuttings of all late-November to Christmas flowering varieties. Some growers use up the old ball-soil from the current year's final potting. It is best to refrain from doing this, to use instead quite new loam, that is, loam that has been cut and stacked at least six months. Two-thirds of such loam and one-third of well rotted leaf-soil will form a sweet, ideal compost for the cuttings, especially if some old mortar rubble can be mixed with it instead of sand. Neither bone meal, soot nor any other artificial manure should be used in the soil for the cuttings. Wait until the first potting, then use some judiciously. Deep, narrow pots are best for rooting single cuttings in and a box or a small frame on a greenhouse stage will answer. The temperature of the house should range from 40° to 50° during the depth of the winter, although several degrees lower or higher, according to the weather conditions, will not do any harm.

The old roots should be kept in a cool, light house, and dry atmosphere. Where cuttings unduly crowd thin out the weakest. The best cuttings are those severed at soil level from suckers growing through the soil in the pot. These suckers should not be pulled up and inserted whole, as shown at *a*, but they should be cut off at *b*; cuttings with flower-buds growing on them at *c*,

Digitized by Google

and those growing from the old stems, *e*, also having buds, should be avoided. The right cutting is shown at *f*, and if the lowest leaf, *g*, and the stem is severed as shown at *h* it will be ready for insertion. Plunge the pots in ashes or coconut fibre *i*, to prevent undue dryness, and ventilate one hour daily at *j*. Remove the cuttings when roots are as advanced as shown at *k*, *k*.

Bringing on the Freesias.

FREESIAS which were planted in August should now be growing strongly. Many people fail with freesias because they do not realise that these plants greatly dislike a high temperature when in growth. Only a very moderate heat is permissible, and this is most usefully employed just when the flower buds first of all appear. As a matter of fact, freesias are nearly hardy, and, if they can be protected from severe frost, will grow quite as well in a frame or an unheated greenhouse. Naturally, in such places, one cannot expect very early flowering. When freesias are growing actively they simply must have plenty of water, and it is rather a good plan to let this be just off the chill. Any neglect in the matter of watering will cause the leaves to turn yellow and flower buds to shrivel up. Whenever the weather is favourable, air should be admitted freely. Then one cannot well keep the plants in too light a position. The top shelf of a greenhouse where they will be close to the glass is best for the plants. When freesias are grown in rooms where, by the way they often do very well, they should be kept in front of a sunny window.—S. LEONARD BASTIN.

FACTS ABOUT FERTILISERS

THE proper application of suitable manures is an important feature in the routine of the garden. Fertilisers used in a careless manner will often do little good and, in some instances, might really produce harmful results. Here are a number of points which it is well to bear in mind when the value of any particular manure is under consideration. For the purpose of convenience the fertilisers are classed in three groups—animal, vegetable and mineral, the latter including the purely chemical fertilisers.

Animal Manures.

Horse and Cow Manure.—In many country districts, and even, at times, in towns, horse and cow manures are easy to get. The former is, of course, of a heating nature, and, on this account, is extensively employed for the making of hot-beds. Owing to the opening effect which horse manure has on the soil, it is more suitable for a heavy than a light ground. Never put it in a fresh state close against the roots of plants, and when employed for potting mixtures it is well to use it after it has lost most of its heat, as would be the case if it had been taken from an old hot-bed. Cow manure is of a cold, sticky nature and may be worked into a light soil with great advantage. To form a liquid stimulant cow manure is very useful, and the best way is to put some into a bag and then stir this about in a tub of water until a deep brown liquid is secured. In use this can be diluted until it is the colour of tea of moderate strength.

Pig and Sheep Manure.—Both of these are very useful and may be dug straight into the soil without the least risk. In the case of a light soil do not work too much straw or bedding into the ground with the manure; on heavy land a certain amount of the bedding material will help to open up the land. Sheep manure may be used in the making of liquid fertiliser as described in the case of cow manure. Well dried sheep manure is often mixed with potting composts with good results, but do not use it in a fresh state.

Poultry Manure.—This is a very powerful fertiliser and should be used with great care, otherwise serious injury to crops may result. Quite the best plan is to mix it with equal parts of ashes and sand, adding if possible, a very little quicklime. Spread this mixture evenly over the surface of vacant ground. If used for potting composts, double the quantity of sand or soil mixed with the poultry manure. Even then it should not be employed in a fresh state, but should be heaped up for some time until the whole mass has changed into a mould. This may then be mixed with the potting soil, allowing about a 5in. potful to each bushel.

Guano.—When genuine, guano is extremely rich in plant foods. To make sure that you are getting real guano it is wise to buy from one or other of the well known firms. In recent years the supply of really high-grade guano has decreased and there is much inferior stuff about. Guano may be spread on soil, the rate of application being from 1 oz. to 3 oz. per square yard. Whether the smaller or larger amount should be used depends on the quality of the guano, and this the grower should ascertain. Guano is best given to pot plants in liquid form (½ oz. should be dissolved in 1 gallon of water). The fertiliser should never be applied more than once a week, and not at all until the plants have practically filled the pots with roots.

Bones.—Gardeners should not overlook the value of bones as fertilisers. These are very rich in phosphates, which are, of course, extremely useful in connection with fruit culture. The bone-meal which one can buy is, obviously, more soluble and, therefore, quicker in action than the actual bones themselves. None the less, bones, so long as they are not too big, are always worth working into the ground, and it is remarkable to see the way in which the roots cling round them. Small fragments of bones may be used with great advantage in the case of pot plants. Large pieces should not be used, as these tend to harbour soil pests.

Vegetable Manures.

Garden Rubbish.—Most kinds of garden rubbish have a considerable fertilising value. It is a good plan when taking out trenches to throw all rubbish that will decay harmlessly into the bottom. Cabbage stumps, tree clippings and any strong perennial weeds should not be used for this purpose. The trench can be filled to within about 6ins. of the top and, after a thorough treading down, the material is covered in with soil. Another way of using garden rubbish is to pile it up in a heap and then scatter lime over it, turning it frequently until the whole mass has well rotted.

Leaf-soil.—Leaf-soil is a rich fertiliser and is also useful on account of its power of retaining moisture. If there is potting to be done a heap of decaying leaves should always be kept on hand. This should be stirred now and again and, as the months pass by, excellent mould can be sifted from the mass. Throw back that portion which does not pass through the sieve. It pays to dig as many leaves as possible into the open ground and thereby secure a considerable enrichment of the soil. Oak, beech and horn-beam leaves are the best, but the foliage from any deciduous trees is not to be despised.

Lawn Grass.—Where lawns are mown once a week during the season it is a good plan to leave the clippings on the grass. If this is not done lawn clippings may be spread on to soil and finally dug in with advantage.

Green Manures.—When ordinary fertiliser cannot be obtained soil may be greatly improved by sowing a green manure, at almost any time when the land is unoccupied. Mustard, rye grass or clover are suitable; these should be dug in before they flower. Often it is not possible in a small garden to spare the land for this treatment, but the soil is greatly enriched by the process.

Seaweed.—Those who live near the coast should realise that, in seaweed, they have a really useful maure. Very often the amount of salt in it renders it somewhat unsuitable for placing straight away on the land. The best method of preparation is to form a heap of alternate layers of seaweed and soil, each about 6ins. deep, with a light dusting of lime over each layer. After a few months turn the mass over and when it seems fairly decomposed spread it on the land. Seaweed will benefit any vegetable crop, but is especially useful in the case of asparagus.

Mineral Manures.

Coal and Wood Ashes.—Coal ashes have practically no value as fertilisers, but they are of service when, in small quantities, dug into heavy soil. Pure wood ashes, on account of the large amount of potash they contain, are really useful. Dig them straight into the soil or mix with the soil used in potting. Never leave ashes about in the rain, as this tends to lessen their fertilising value. When sifting wood ashes, remove any lumps of charcoal that may be brought to light, and carefully put these on one side. Small lumps of charcoal may be usefully worked into the soil used for potting, and it is especially beneficial in the case of chrysanthemums. Where there is plenty of charcoal it is an excellent plan to put some just over the layer of crocks that are used in connection with the drainage of the pot.

Soot.—Soot is most useful, both as a fertiliser and as an insecticide. It may be dusted over the ground at the rate of 1 bushel for every 3 or 4 square rods, when the land is vacant or after sowing. It is good for almost any vegetable or fruit crop, and may be employed as a liquid manure for pot plants.

Lime.—Lime tends to act more as an agent in the soil rather than as a fertiliser in itself. However rich land may be in plant foods, most crops starve if there is a deficiency of lime in the soil. Generally speaking, it should be part of the routine of the garden to dress vegetable land with lime every three years. The lime should be used in a slaked state, and there is no need to dig it in deeply, as it has a tendency to sink. Gas lime is not so useful as ordinary lime, but it has greater powers as an insect destroyer.

Mortar Rubble.—Those who garden on heavy ground should not lose an opportunity to secure mortar rubble. This not only contains certain fertilising elements, but it is also extremely useful for opening up the soil. Mortar rubble may be mixed with potting soils with advantage. Pass through a ¼in. sieve before use.

Salt.—Salt certainly has a manurial value, but it should be used with care, as an excessive quantity may easily kill a plant. It is well to mix the salt with sand in equal parts and to scatter this over the soil at the rate of about 2lb. per rod. Used in this way the salt helps the crops—especially cabbages and asparagus—and, still further, checks weed growth.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Owing to the number of hints which are sent in, we desire that, in future, each hint should be sent in on a post card, and should be limited to 150 words. Payment for these hints is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF-GUINEA HINT

Rambler Roses on Poles.

This is a good method, I find, for the training of rambler roses on poles. After taking down the roses and cutting out the old growths and weak shoots not required, I lay out new shoots on the ground, to get them into their different lengths. I then commence with the shortest shoot and twine it round the poles, and follow on with the longer lengths, so that each keeps the other in position. The longest shoot is kept secure by putting a piece of tarred twine round the post. If some of the shoots do not seem secure enough, a piece of twine may be put lower down. I think this is a quicker method than putting bands of twine round poles and tying each shoot individually, as it saves a great amount of twine when a large number of roses have to be dealt with on poles, and it is much more natural-looking. It is best to use the tarred twine, as it is not affected by weather conditions. When roses are trained by this method it is just a case of cutting the twine when roses have to be taken down again, and they come away quite easily.—W. J. B.

How to Tie Small Trees and Shrubs to their Supports.

Strong gales are often experienced at this time of the year, and a lot of damage is done to standard rose trees, half-standard rose trees, small shrubs and also small trees by simply tying them with naked string to their supports. The trees get blown backwards and forwards, causing the string to cut into the bark of the tree, bruising the stem of the tree and causing it to bleed. The result is death to the tree, or canker. Get a piece of old water hose-piping, cut it into pieces 1in. long, then cut down one side of it, pull it open, then slip it on to the stem of the tree or shrub. This will form a rubber band. Tie the string twice round the band, then fasten it strongly to its support. This will prove valuable to all.—B. R.

Mealy Bug on Vines.

This pest is by no means easy to eradicate once it has got a good foothold. The best method I have found yet is, after thoroughly cleaning the house with soft soap and paraffin, removing all loose bark from the rods, then wash them with a solution of XL-All Insecticide, double strength, finally painting them over with painter's knotting. This, when dry, forms a thin glaze, starving any insects that may be hidden under the bark. The rods, being shiny, show up any stray insects that may be lurking about in the spring, when they can be touched with a brush dipped in methylated spirit.—F. D.

A Raspberry Manuring Hint.

When manuring your raspberries, bear in mind that they like heavy but well drained soil; therefore, pig manure is just the thing for them. The biggest raspberries I have ever seen were grown on the site of a year-old pig manure dump. The good thing about pig manure for mulching is that it does not dry and become a husk as quickly as cow and horse manure. A good artificial for raspberries is basic slag, but there is no need to get it on before January. No good is done by early applications being washed away by the autumn and winter rains. Further, I am told that basic slag is considered now to be much quicker in action than it was formerly thought to be.—S. P.

Dish of Rhubarb on New Year's Day.

Get an old barrel (an apple barrel does well) and put it in a corner of your greenhouse or toolshed. Lift a good crown of rhubarb and place this into the barrel; give a good watering and cover up by placing a bag over the top of the barrel. Keep the crown moist by watering occasionally. I have done this for years and always had my dish on the first day of the year.—W. T. S.

A Remedy for Rough Hands.

To keep the hands from becoming rough during frosty weather, take chopped beeswax 4 oz., olive oil 2 fluid oz., place in an oven until melted; when cool enough to handle, roll into a ball and use by rubbing lightly over the hands after washing.—S. G.

Killing Wireworms.

Now that all the root crops are lifted and stored, many will look round to find a suitable means of getting rid of wireworm. An old plan and a very good one is to slay him with kindness. Insert among your plants tempting lumps of linseed cattle-cake as big as walnuts, just lightly buried in the earth. He will feed greedily on this until his jacket becomes over-distended. What follows is better imagined than described: but there is no more wireworm. Many remedies are advocated, but this is the simplest.—W. A. W.

"THE GARDEN" CROSSWORD—III

Two Prizes of ONE GUINEA will be given to the first two correct solutions opened on the morning of Thursday, December 9th. If no correct solutions are sent in, these prizes will be awarded to the first two in order of merit that are opened. All envelopes must be marked "Crossword" on the outside and addressed to THE GARDEN, 20, Tavistock Street, Strand, London, W.C.2. No other communication must be enclosed in this envelope.

ACROSS.

1 Composite plant of the ox-eye daisy family.
12 An affirmative.
13 Plant of the crowfoot family.
14 Employs.
16 Neuter pronoun.
17 Insect in the caterpillar state.
19 A vein containing metallic ore.
20 A subaltern (abbr.).
21 Reserves (abbr.).
22 To implant.
23 A meadow (var.).
25 The sweet potato.
26 Slippery fish.
28 Sixth musical note.
29 Kind of clayey rock.
33 Lichen.
36 A South American potato-like plant.
37 Garden vegetable.
39 Drug extracted from the white poppy.
41 Hardiest.
43 Another name for "corolla."
44 A berry-bearing shrub.
46 Require.
48 Railway (abbr.).
49 Name applied to several varieties of plum (pl.).
52 Annual plant, bearing pulse used for food.
54 Decayed vegetable matter used for fuel.
56 A liqueur prepared from anise seed.
57 Accomplish.
58 Pronoun.

DOWN.

1 Variety of cabbage.
2 A very fine green tea.
3 Hollow, jointed plant-stems.
4 South Australia (abbr.).
5 The indigo plant.
6 A stinging weed.
7 Trade Mark (abbr.).
8 An evergreen shrub much in evidence at Christmas.
9 Girl's name.
10 An English wild-cherry.
11 Unwholesome vapours arising from putrescent matter.
15 Germs of plant-life.
18 Calves' flesh.
24 A shade tree.
26 Bad potatoes have them.
27 The trembling poplar.
30 Frigidly.
31 An aromatic plant.
32 Ornamental stand for holding flowers.
34 Boo (reversed).
35 "Bladder Campion" or "Catchfly."
38 Preposition.
40 A Mexican India-rubber tree.
42 That is.
45 Same as 26 across.
47 A palm fruit.
50 Consumed.
51 Dig (reversed).
52 A Chinese mile.
53 Plural suffix.
54 Italian river.
55 Forenoon.

OUR SERVICE BUREAU

Though so many subjects are dealt with in each issue of THE GARDEN, *it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, there is always information available from a staff of expert contributors and consultants; and there is no charge for this. It is one of the additional means of service which* THE GARDEN *is glad to render to its readers.*

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope and the coupon, that will always be found in each issue, shall be sent with the enquiry. We would point out, however, that we cannot undertake to supply readers with plans and designs of gardens, but will willingly assist in giving suggestions for planting.

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2.*

We have selected the following enquiries, with their answers, as being of more general interest, and therefore worthy of publication.

How to Treat Soils Infected with Club Root.

I shall be much obliged if you will kindly advise me how to treat soil badly infected with club root. Our kitchen garden is on ground that was used as allotments during the war and then allowed to go out of cultivation. For the second year running we find it impossible to grow any sort of cabbage. The ground has been trenched and treated with lime and the plants put in were healthy at the time of planting.—B. E. B., Lindfield, Sussex.

The only effective way of treating ground which is infected with club root, is by digging the soil over at once, leaving it in the rough state and applying a good, heavy dressing of lime. The ground should be allowed to lie fallow during the winter, and the lime allowed to wash in. Next year, no cruciferous crops, such as cabbages, cauliflowers, broccoli, etc., should be grown in this ground, but potatoes may be grown. This is about the only way of getting rid of this troublesome disease.

Treatment of Coltness Gem Dahlia.

I have just lifted my Coltness Gem dahlia. I am surprised at the size of the tubers. Shall I have to plant the whole bunch next year, or do I split them into separate units? Could I start them in a cold frame, and at what time of next year? I have stored them in a box of dry soil.—K. G., Barnsley.

Keep frost from the dahlias. You may plant the tubers intact, or start the new growth in a frame and divide the tubers; or you can start the new growth so and take off some of the young shoots when about 4ins. long, root them in sandy soil in a gentle heat and plant the old tubers too. Place them in the cold frame at the end of February.

Black Vine Weevil and How to Destroy It.

You have been so kind as to give me valuable advice on previous occasions that I venture to ask you can I use carbon bisulphide among roots of vines to destroy the larvæ of the black vine weevil without injuring the roots? I am not actually plagued with them, as they do not visibly affect my vines or grapes, but the larvæ get into fern roots, begonia bulbs, etc., and do a lot of damage, and I am thinking I may destroy all the larvæ by injecting bisulphide in the borders.—W. C., Guernsey.

You may use carbon bisulphide; it will destroy all insects in the soil. Make holes with a small stick about 1ft. deep and 2ft. apart, and pour into each hole 1 oz. of the liquid bisulphide. Fill up each hole made with fine soil. Keep lighted matches, candles or other lights away, or there may be a serious accident, as the liquid is very inflammable.

Levelling Uneven Ground.

The article on digging and trenching in your issue of October 16th touches upon the subject of levelling uneven ground. I am just now engaged upon the clearing of part of my garden with a view to making a full size grass tennis court, and by the time the transplanting of fruit trees and evergreens is complete the ground will be a series of hills and hollows, and I am told by my friends that I will never attain the necessary levelness for a tennis court without professional assistance, which I cannot afford. Can you give me any guidance as to how large area levels are obtained? I fear trusting to the eye alone will not give us the real levelness for a tennis court. We have stripped the place of all old grass intending to dig all over and sow with the best lawn grass seed next spring. What would be the best time to dig and to what depth should we dig? The soil is clay and fairly quick drying except at one end close to a high wall, and the place generally gets plenty of sun. I have already derived much helpful information from your Service Bureau columns as to lifting, dividing and transplanting, and I shall be grateful for any hints you can give me as to the best method of obtaining lawn levels.—S G., Dublin.

You need not despair of getting your ground properly levelled. First fill in soil to level individual holes, thoroughly treading the soil as each thin layer is put in. Have the soil, at the finish of this part of the work, about 3ins. higher than the normal level—the part not dug up—then begin at one corner, using pegs, straight-edge board and spirit level, and level to the other corners, driving in pegs for the purpose of resting the straight-edge on them; but level so that one end will be 2ins. or so higher than the opposite one. This is done to prevent water ever lodging on the surface. Fill up with soil to the tops of all the pegs before drawing out any of them. Dig an ordinary depth only now, or soon. From time to time fill up any hollows forming.

Plants for a Narrow Bed by a Wall.

Would hypericums prosper in a very narrow bed of light soil against the wall? It would get no sun until midday, but from that hour onwards it would be baked in the summer. As the bed consists of a very narrow strip between a wall and a brick path, I intend to plant an ampelopsis at one end and an early-flowering climber, such as Jasminum nudiflorum, at the other, filling up the rest of the space with a low-growing evergreen able to make the most of the situation. There is plenty of soil in depth but very little in width.

Can you tell me the name of a deciduous plant to form a hedge 2ft. or 3ft. high, for light soil, transparent enough to let winter sun through to early spring flowers and thick enough later on to protect them from being burnt up in August?—R. S. G. E., Colombes (Seine), France.

Hypericum will probably suit the position you mention exceedingly well. Such species as H. patulum Henryi or Moserianum will probably be the most suitable. These shrubs are not too vigorous growing and do not require a great amount of space.

We should suggest that for your hedge you try either hornbeam or beech. These can be kept at a height of about 3ft. if properly trimmed every year. Hornbeam might prove better than beech, in that you want the hedge to be open in winter. Hornbeam will give adequate protection from the sunlight in the summer, when it is fully clothed with the leaves.

Climbing Shrubs for a Porch.

Having recently, and to my delight, "discovered" THE GARDEN, I am taking advantage of your Service Department to learn the following: What climbing shrubs could be grown one on either side of my doorway? Would it be necessary to erect a trellis, or could they be trained to the bare wall? Please give in brief, if possible, the habits of your suggested shrubs. In the remaining part of the bed I propose to plant a small variegated laurel—one on either side. Would this be detrimental to the healthy growing of the climbers?—P. C., Woodford Green, Essex.

We suggest two bushes of Pyracantha coccinea Lalandei for the position which you mention. This is an evergreen shrub carrying very neat, small, shiny green leaves whose beauty is greatly added to in autumn by enormous clusters of bright, shiny red berries. It is a shrub which does particularly well against a wall, being of a bushy and upright habit. It is a particularly accommodating plant, and generally is not difficult to establish. Another good climber which looks very effective against an archway is Forsythia intermedia spectabilis, which in early spring is covered with clusters of golden yellow flowers. It is deciduous, and looks rather bare in winter. In spring the yellow flowers come before the leaves. Still another useful climber is to be found in the jasmine, J. nudiflorum. Many of the ceanothus, such as C. thyrsiflorus or rigidus, are very neat-habited climbing shrubs with their rather attractive bluey green leaves and tight clusters of deep blue flowers. This list will probably help you to select one or two plants.

Pruning of Cordon Fruit Trees.

I have just bought and planted a cordon apple, pear and plum tree; they are four years old and are about 9ft. high; also a bush apple and plum tree. Shall I have to prune them now or in the spring, and shall it have to be the leading upright spur? I have also two apple bush trees and a cherry tree, planted last spring; they have made good growth. How shall I prune them? I only started gardening last spring, and I have found your paper very useful and well worth the money since I started to get it some time this summer.—E. H. W., Yorkshire.

The newly planted cordon apple, pear and plum trees should be pruned a few weeks after planting. At 9ft. high they seem very tall for their age and probably have been let run a little too high in past seasons. However, the pruning now required is to shorten the leading or extension shoot on each by about one-third and to cut back all other young side shoots to two or three bottom buds. The bush apple and cherry trees require similar treatment, each branch being treated as a cordon—that is, the leading young shoot on each branch should be shortened by about one-third and all side shoots on them cut back to two or three buds at the base. With these bushes, aim to keep the centres open and free from crossing growths and the branches evenly spaced, so that the tree is balanced and shapely.

FACTS ABOUT FERTILISERS

(*Concluded from page 704.*)

Nitrate of Soda.—This fertiliser is especially useful for promoting leaf growth, and it may be usefully employed in the case of all members of the cabbage tribe. Nitrate of soda may be applied at the rate of 3lb. per square rod, dividing the quantity into two applications with an interval of six or eight weeks. If the chemical is applied to vacant ground it is well to sow a crop of mustard, which is subsequently dug into the land. Nitrate of soda, being very soluble, is readily washed away by heavy rains and the roots of the mustard crop help to keep it in the soil.

Sulphate of Ammonia.—This does not act so quickly as nitrate of soda, but, being a nitrogenous manure, it may be applied for the same purpose and in a similar manner. When sulphate of ammonia is employed as a liquid fertiliser it is much quicker in action and may be employed at the rate of 2 oz. to each 3 gallons of water.

Superphosphates.—This is especially fine for tomatoes where a little may be sprinkled on the surface of the soil just after the setting of the fruit. It is much better to apply a small quantity about every ten days rather than to put a bigger amount at one time. On the open ground, where superphosphates can be highly recommended for the kitchen garden crops, it should be applied at the rate of 5lb. or 6lb. per rod. If possible, apply in the early spring, as this will bring the best results.

Kainit.—This is a potassic salt which is highly useful for vegetable crops. It should always be applied to the open ground in the autumn. A suitable rate of application would be 5lb. per rod. Neither kainit nor any of the three preceding fertilisers should be allowed to come in contact with foliage, as they are likely to have a burning action.

S. LEONARD BASTIN.

CATALOGUES RECEIVED.

We have received from Messrs. Little and Ballantyne, nurserymen and seedsmen to H.M. the King, Carlisle, a copy of their annual catalogue of nursery stock, which we commend to the perusal of intending purchasers of plants of all descriptions. Among the screen plants we observe very prominently their new poplar Populus generosa, which as a quick-growing plant bids fair to supersede all others for screening purposes. Topiary work, too, for the small garden is profusely illustrated, roses, ornamental shrubs and fruit trees are conspicuous features, and it certainly is a list that ought to be in the hands of every gardener.

Messrs. A. J. and C. Allen, Bowthorpe Road Nurseries, Norwich.—A comprehensive rose catalogue in which the roses are well classified and carefully described. Interesting notes are given on novelties of 1926 and on the recent improvements and failures in the rose world.

Messrs. Austin and McAslan, Glasgow.—Two catalogues, one of alpines, herbaceous and other hardy plants, including a good collection of herbaceous peonies; the other of coniferæ, ornamental trees and shrubs, rhododendrons, hedging plants and fruit trees.

Messrs. J. Forbes, Hawick, Scotland.—An extensive list of alpine and herbaceous plants. Numerous uncommon plants are listed, as well as good collections of primulas, saxifrages and auriculas. A planting plan of a herbaceous border is given.

Messrs. D. and W. Croll, Limited, Dundee.—An interesting and useful illustrated garden booklet, which is full of information, has been received from this firm. The hints on the planting and management of roses should prove of service to all amateurs. Roses, perennials, shrubs and nursery stock are listed.

SANDERS & CO.,
Sundial House,
365, EUSTON ROAD, LONDON, N.W.1

Please mention THE GARDEN *when writing.*

WE have already drawn attention to the suitability of garden requisites as gifts at Christmas time and as it is a topic of some interest we enlarge still furtheron our list of suggested items. Really enthusiastic gardeners will welcome and value a present, however small, which will help them in their garden during the coming year or add to its beauty. There is no lack of choice and no doubt many of our readers will think of more novel and useful gifts than we suggest here. There is only one point which we might stress and that is that the gift should be a useful one.

Seeds.

AT this time, with the arrival of seed catalogues by every post, and the making of a selection for one's own garden, why not choose a few packets of choice annuals for your friends? The gift is not an expensive one, yet, on the other hand, it indicates your appreciation of your friend's effort, as a gardener, which your friend, in return, will value. Select those kinds which you think will suit conditions in your friend's garden and varieties which you are almost sure he does not grow, but which he has probably expressed some hope to try on some previous occasion. No matter what kind of a garden your friend may have, or in which branch of gardening he may be interested, a few packets of summer-flowering annuals will not come amiss. You can select those sorts which make good edging plants, or those which make a blaze of colour in the rock garden, or again those which will add beauty and colour to the permanent border. If your friend has a greenhouse your choice may be wider by the inclusion of a few half hardy and tender kinds to provide him with a bright display in the early spring months in his house. Do not confine your gifts to flower seeds, but include a few packets of vegetable seeds if your friend goes in for vegetable culture and what keen gardener does not? A few packets of tomato seed, seeds of a new variety of culinary pea, such as that excellent variety Giant Stride, or some up-to-date variety of carrot, turnip, cabbage and so on will be welcome. The selection is endless.

Garden Etceteras.

THERE are any number of items which for convenience sake may be grouped as garden etceteras, any one of which will make an admirable gift to a gardening friend. These include such gardening requisites as tools, gardening gloves, a small frame, a length of hose, a sprayer, a collection of plant labels, netting for the support and protection of wall fruit trees, a load of gravel or sand, a bale of peat moss litter, a bag of artificial fertiliser or a tin of spraying material. The range covers a wide field and each will form a useful gift which is not expensive. What gift can be more suitable than a fork or spade? Both are necessary in any garden and they are articles of general use. If your friend is amply supplied, then a pair of secateurs for pruning his trees, shrubs and roses. This is a gift which will be greatly valued, as it is a tool which the ordinary gardener does not purchase until his stock of plants demands the use of secateurs for quickness in pruning and not the old-fashioned slow method of knife pruning. A small hand fork for weeding purposes will always find service in any garden and it makes an inexpensive gift. There are many manures from which to select, but select general purpose fertilisers.

The "Spade Scraper" Pocket Pipe Cleaner will shortly be on sale at Tobacconists, etc.

Ask your garage to fit the car pattern Spade Scraper under the step of your car. Price 4/6 inclusive.

A year or two ago one of our readers wrote to say that the most useful gift he had received at Christmas was a load of farmyard manure. That is a sensible and very useful gift, but nowadays very difficult to procure and the next best is a gift of a substitute, such as Wakeley's Hop Manure. Then come all the chemical fertilisers, the nitrogenous group, of which sulphate of ammonia is probably the most serviceable for general purposes, the phosphates, superphosphates, the potash group and so on. Each plays its part in adding to the fertility of the garden and to the success of the fruit, flowers and vegetables.

Books.

HAVE you ever thought of giving a book on horticulture as a Christmas gift to a gardening friend? It is one of the most suitable of all gifts. It may take many forms. It may be an epitome of gardening or horticulture, a book that can be in constant use as a work of reference when any doubts or difficulties spring up. At least one such work should be on every gardener's bookshelf, for no one is so expert that he can hope to know or remember everything. It may be a book on some particular branch of gardening or on some special plant in which you know that the gardener to whom it is to be presented is interested. Dozens of useful books of this class exist at moderate prices. It may be a book on gardens in general, a book that is not only full of useful information, but is also charming to read through during the long winter evenings or during days when there is not much to look at in the garden. Whatever the book may be, you may rest assured that it will be useful and appreciated by the recipient. It helps the imagination and also the knowledge and lore of the gardener, besides giving opportunity for discussing the subject on which it is written during many happy hours on long winter evenings. Although a gardening book may not be such a good teacher as experience, yet they should run hand in hand. In fact, a gardening book makes an admirable Christmas gift.

Bird Baths and Garden Ornaments.

ONE of the most acceptable of all Christmas gifts to one of your gardening friends would be a bird bath or garden ornament. These ornaments (provided they are well chosen) add beauty and interest to any garden. There are bird baths of all shapes and sizes, made in York stone, Bath stone, artificial stone and pottery and their prices vary likewise, ranging from the small sum of 10s. 6d. for shallow, dish-like bird baths, to £10 and onwards for pedestal bird baths. What would be more appreciated than a lawn bird bath of circular design with a small ornament, such as Pan or a kingfisher, placed in the centre of it! The tall pedestal bird baths, which cost about £3 to £5 would be gladly received by anyone who has a formal rose garden or a terrace in front of his house. A sundial, a small statue and several stone vases or pots are other suggestions for presents. Among these one could select a few large square stone flower pots (they cost £2 onwards), which could be used for tub plants, such as hydrangeas, fuchsias, bay trees; or vases for the corners of a balustrade; or long rectangular troughs which look so effective when filled with bedding plants; or a small figure for the centre of a lily pool. Some of these small statues which are now on the market, are quite inexpensive and although they are made of artificial stone, the material which is used in their construction does not suffer from the effects of frost. Lead figures cost considerably more than those made of stone, but on the other hand they last indefinitely and look well in any type of garden. Some people would be delighted with one of the quaint little stone animals which are now being made; squirrels, frogs, lizards, rabbits, etc.

Make Your Garden Beautiful in Winter.

Notes from Maidstone.

COOKING APPLES.

All Apples may be cooked, but not all are edible. Some are pasty and flavourless, others brown and woody. We can thoroughly recommend Golden Noble for autumn use, this cooks a clear amber yellow,. and Thomas Rivers, in use till December, of unique fragrance. Of these, beside the usual forms, we have some extra large pyramids, 6ft. high and well developed, at 15/- each.

VEGETABLES OF QUALITY

THE recent articles in the Press regarding the health-giving qualities of various kinds of Vegetables should emphasize the importance of growing only the best varieties.

Carters strains of Choice Vegetable Seeds have never been better than they are to-day; this is brought about by selecting only the best varieties; thus maintaining the high standard of quality so necessary for culinary purposes.

VOL. XC.—NO. 2871. DECEMBER 11, 1926. PRICE TWOPENCE.

NOTES OF THE WEEK.

The 1927 Daffodil Show at Vincent Square.

THIS April fixture, so eagerly looked forward to by all daffodil enthusiasts, will next year embrace a number of new features which will still further commend the occasion to those who mark the date (as one marks "Chelsea") as one of *the* outstanding events of the year.

Hitherto the "man in the street" (and the lady in her home) has been bewildered by the seemingly endless array of varieties grouped by experts to form striking and harmonious general exhibits. It is most difficult under such conditions for the ordinary person to form any idea as to how any given individual variety would look set among familiar home backgrounds. Next year we are to have two classes for "cut flowers," *e.g.*, a bunch of flowers shown *as* a bunch of flowers, for comparison and competition with other bunches of any other variety—not three chosen flowers against somebody else's three chosen flowers of the same technical classification. This is a good beginning. We hope to see the feature well patronised and extended in future years. It is just the thing to interest and attract amateur growers. The market grower is also to be catered for more liberally by the inclusion of classes for packed boxes of (1) trumpet varieties, (2) Leedsii varieties, (3) coloured varieties, and (4) poets. In addition, there will be similar classes for smaller quantities of each. In the past there has been all too little interest displayed in these classes for market growers. It is a very good move to encourage growers to pack well and attractively so that the boxes arrive at destination in first-class condition; but if the R.H.S. would earn the undying support of market growers, let them conceive a class to encourage *buyers*, *e.g.*, the best boxful for 5s., 10s. or 20s., carriage paid to destination. Buyers would be amazed if they knew the value our British growers can give. Frequently growers receive less than one halfpenny a bunch for flowers that are retailed at 6d. and over.

When the Snow Comes.

GENERALLY speaking, snow is to be regarded as beneficial to plant life in that it forms a fine protection against frost. Under a few inches of rather loose snow plants suffer little or no harm, even from a frost that may be very severe indeed. Now and again snow does act hurtfully to small plants, and the trouble generally arises in this way. A fall of snow is followed by a slight thaw, and this is then succeeded by a frost. As a result there is formed a continuous surface crust of ice which completely envelops the plants. If this crust remains for some days the plants may suffer badly owing to the fact that they are quite unable to get any air. When the snow finally disappears there is little to be seen save a few rotten leaves where the plants should be. Hard crusts of snow should not be allowed to remain unbroken over any plant. Much may be done to break up the mass by inserting the sharp point of a fork at intervals and moving the fragments about a little where this can be safely done. Generally it is a mistake to remove the pieces of ice altogether, as quite likely parts of the plants may be frozen right into them, and if the chunks are wrenched away serious damage will result.

Evergreen trees and shrubs of all kinds are liable to serious injury from snow, which breaks or distorts their branches. Deciduous trees are much less likely to suffer, as the snow cannot collect to any great extent on the bare branches. The greatest risk occurs when snow falls in calm weather with the temperature just about at freezing point. All evergreens may then suffer badly, but those which are most likely to be harmed are the spruces and others with horizontal branches. Here the leaves are so arranged as to offer a considerable surface on which the snow can lie. Damage may be prevented by shaking the branches with a pole while the snow is still loose. If the branch shows signs of beginning to yield, shake the snow off and support the bough by suitable means. Where there has been an actual breakage smooth off the wound as much as possible and then treat it with Stockholm tar. When snow melts under the action of bright sunshine it will often damage the foliage of laurels, etc. Here it is an excellent plan to go round and shake the shrubs vigorously so as to get away as much of the snow as possible.

HAVE YOU

- ¶ *Renewed your annual subscription to* THE GARDEN?
- ¶ *Lifted and prepared your seakale for forcing?*
- ¶ *Inserted cuttings of your perpetual carnations?*
- ¶ *Rolled, renovated and killed all weeds on your garden paths and walks?*
- ¶ *Pruned your gooseberry bushes?*
- ¶ *Top-dressed your apple and pear trees with a dressing of basic slag at the rate of 4oz. per square yard?*
- ¶ *Taken into a warm greenhouse your early bulbs, such as Roman Hyacinths and Paper White Narcissi?*
- ¶ *Fumigated your greenhouse with nicotine compound in order to keep down insect pests?*
- ¶ *Removed runners, as well as dead and decaying leaves from your strawberry plants?*

Zinc Labels.

A CORRESPONDENT has been kind enough to send us several examples of the old zinc label which he uses in his garden with great success. By boring holes in them and attaching stout wire, he raises the actual labels above the ground. The labels are carefully cleaned with emery paper, written on with a quill pen, and then varnished all over with transparent varnish. The labels are allowed to stand a week before placing in the garden. From the samples sent, which our correspondent tells us have been in use for several years, it is obvious that his method is simple, economical, and practically everlasting. In addition, no corrosion or oxidising of the lettering takes place owing to the varnish. Some of our readers may like to label their plants in this way.

The Crossword Prizes.

THE two prizes of One Guinea each offered to the readers who sent in the first correct solutions opened to THE GARDEN Crossword No. 2, which appeared in our issue of November 27th, have been awarded to

Mrs. Yonge,
Wanboro' Lane,
Cranleigh, Guildford.

and

Mr. Gillies,
62, Carleith Quadrant,
Glasgow, Scotland.

To each of whom a cheque for that amount has been sent.

SCENTED FLOWERS FOR YOUR GARDEN

IT will add greatly to the amenities of a garden if a portion of it can be devoted entirely to sweet-scented plants. Whether it is large or small, such a plot should be, if possible, enclosed by a hedge or wall; but if this is impracticable, it should be at least definitely divided from the rest of the garden even if only by a trellis. If there is a hedge it may be of lavender, rosemary or sweet briar, the latter being either the common sort or the more showy—but perhaps less fragrant—Penzance varieties. The briars, of course, have the undoubted disadvantage of being deciduous, but nothing is more delicious than their odour after a summer shower. In the mildest parts of the country the myrtle makes a beautiful evergreen hedge, but in the colder districts it cannot be grown safely save against a south wall, and the same may be said of Lippia odorata, the lemon-scented verbena. Other scented shrubs suitable for walls are the winter-flowering honeysuckles, Lonicera Standishii and L. fragrantissima; Chimonanthus fragrans; Veronica salicifolia, the long spikes of which are redolent of honey; Ribes sanguineum, the flowering or Indian currant; Philadelphus coronaria (syringa), Choisya ternata, Calycanthus floridus (delightfully spicy), Osmanthus Delavayi and Viburnum fragrans. Not all these are customarily reckoned among wall shrubs, but if they can be allowed plenty of room and are judiciously pruned they may be grown as such. For the trellis, if there is one, or to clothe poles in front of the hedge or wall, there are honeysuckles (the varieties of Lonicera Periclymenum), Jasminum officinale, Clematis Flammula, Lathyrus grandiflorus (the sweetest of the everlasting peas) and, of course, roses, among the most fragrant of which are tea ramblers Mme. Alfred Carrière, Gloire de Dijon and Climbing La France, although the last named is not always a satisfactory grower. Hugh Dickson may be added to the list; it is not precisely a climber, but it is quite suitable for a trellis and its perfume is very fine.

There should be borders within the garden in which are to be planted the rose-scented double Chinese peonies, Monarda didyma Cambridge Scarlet, Melissa officinale (balm), Œnothera speciosa grandiflora (the sweet white evening primrose), Hesperis matronalis fl. pl. (sweet rocket), Mirabilis multiflora (marvel of Peru), Allwoodii pinks and double stocks. Interspersed between these should be big groups of Lilium candidum, Hemerocallis flava, the scented day lily, and Iris florentina, with, near the front, patches of the double poets or gardenia-flowered narcissus, most strongly perfumed of its kind and the one that dislikes disturbance most. If rosemary and lavender are not grown as hedges, they must find their place in the borders. There are several dwarf varieties of lavender which are suitable for the situation, but the rosemary bushes will have to be replaced by young ones every three years or so or they will become too large. Daphne Mezereum, both purple and white varieties—although the latter is apt to be short-lived—is another little shrub which should not be omitted from any list of scented plants.

As an edging plant for the borders there is nothing better than either the old fringed white or the pheasant's eye pink, but the annual Alyssum maritimum Little Dorrit is a neat grower, and its perfume, if not strong, is very pleasant, while to many persons the smell of that admirable "edger," Nepeta Mussini, is agreeable, although not I admit, to myself.

In the centre of the garden there should be a bed—or beds—of bush and half-standard roses, all specially chosen for their scent. These may be underplanted for spring effect with Campanelle jonquils, single and double, and scented tulips, such as the early Yellow Prince and the May-flowering Ellen Willmott, macrospila, Primrose Beauty and La Merveille, which in summer should be succeeded by a carpeting of heliotrope, mignonette or one of the scented leaved pelargoniums. A summer-house draped with wistaria and roses should, if possible, be a feature in the garden. Failing this, there must be a seat and close to it there should be beds filled with the old crimson clove-scented carnation combined with Nicotiana affinis, backed with roses Maiden's Blush, cabbage and Rivers' musk—all three famous for their sweetness—and edged with the night-scented stock, Matthiola bicornis. The perfume of these plants will make the seat a very pleasant resting-place on a summer's evening. The nicotiana and stocks are, of course, annuals.

If there is a corner of the garden that, although by no means in deep shade is screened from the sun during the hottest hours of the day, a bed of lilies of the valley may be made there, and, in a rather shadier place, one of violets. And, finally, if the paths are paved, thymes—crimson, golden, silver and the varieties of our native Serpyllum—should be grown in the crevices between the stones, where, as Lord Bacon says, they will "perfume the Aire most delightfully . . . being Trodden upon and Crushed."

THE DWARF WHITE SPIRES OF THE DOUBLE-FLOWERED SWEET ROCKET, HESPERIS MATRONALIS.

SOME FRAGRANT PLANTS.

Alyssum maritimum (annual)	Nicotiana affinis (annual)
Heliotrope	Œnothera speciosa grandiflora
Hemerocallis flava	Pæonia sinensis fl. pl.
Hesperis matronalis fl. pl.	Pink Allwoodii
Iris florentina	P. Pheasant's Eye
Lilium candidum	P. Crimson Clove
Malva moschata alba	P. Fringed White
Martynia fragrans (annual)	Stocks, double (biennial)
Matthiola bicornis (annual)	Thymus argenteus
Melissa officinale	T. aureus
Mignonette (annual)	T. coccineum

Choisya ternata	Osmanthus Delavayi
Clematis Flammula	Philadelphus coronaria
Daphne Mezereum	Rosmarinus officinalis
Lathyrus grandiflorus	Ribes sanguineum
Lavender	Veronica salicifolia
Lippia citriodora	Viburnum fragrans.
Lonicera fragrantissima	
L. Periclymenum (and varieties)	

R. E. HEAD.

Lavender: Its Uses and Propagation.

LAVENDER is easy to grow and one of the easiest shrubs to propagate, as, once rooted, cuttings will form large bushes in three years time, and yield a profitable crop of flowers.

Lavender vera is the best type to grow. Another type, with green leaves and deeper blue flowers, is Felgate Blue, and a dwarf type is Munstead Dwarf, but neither of the latter is valuable for cropping as they lack the scent and essential oil of L. vera.

A good lavender hedge may be produced by buying small plants in the spring and planting alternately in a double row, with 2ft. between each plant. This will form a thick hedge in two years time, which will only need the flowers cutting and lightly trimming. If you already have an old bush, and wish to produce a hedge from it, in early autumn cut it back, leaving only about 6ins. of the old wood; before winter sets in stubby growth will have formed from the cut portions. No flowers will be produced the following year, but by August the bush will be covered with long fresh shoots; when these are ripe detach them from the bush, leaving a heel on each, pinch out the growing point and plant in sand in a trench. After one good watering they will need nothing but weeding during the following year, and by September they will have struck and formed well shaped bushes, suitable for planting out as described above.

As long as flowers are needed bushes should only be lightly trimmed into shape, as heavy pruning stops flowering the following year, and produces new growth.

The purposes for which lavender is used vary greatly. The essential oil, produced after distillation, forms the perfume known as lavender water.

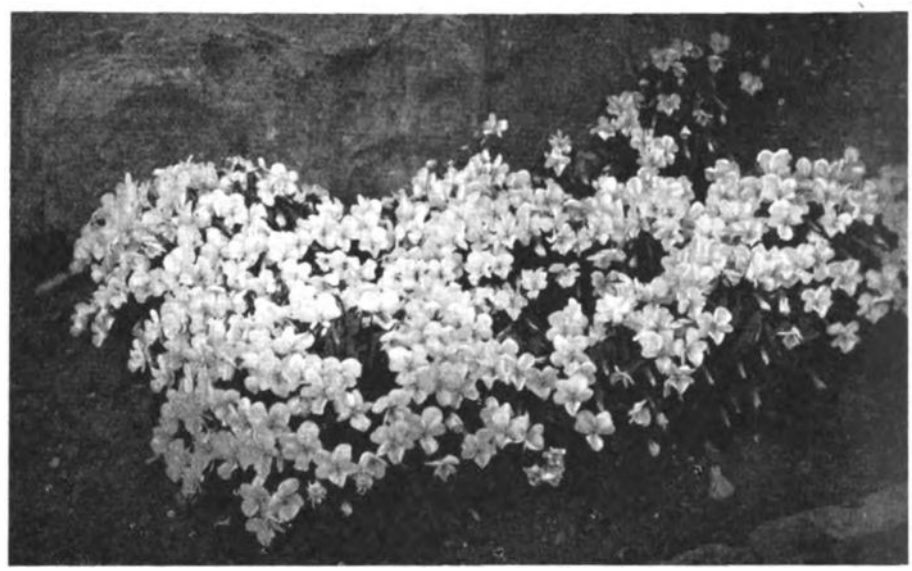
THE ROCK GARDEN

The Small Rock Garden.
The Problem.

ROCK gardening has now become a highly specialised form of horticulture, and I fancy that the beginner, starting with a small piece of rockwork and no experience, must feel bewildered by the multiplicity of plants which are on offer. He generally has to make his choice either from catalogues or at shows, and neither of these sources is very satisfactory, for one does not get a fair idea of a plant's capacities for good or ill, either from a line of print of from a small specimen in a 3in. pot. A flower show, indeed, on account of the crowd and the artificial nature of the display, is an unfavourable place in some ways for good judgment: and as for the lengthy catalogues of nowadays, filled with all sorts of treasures, the beginner cannot see the wood for the trees. In these notes I conjure up an enthusiastic beginner, whose experience and whose rock garden are equally small (the latter, say, 12ft. to 15ft. by 6ft. to 8ft.—these figures are the Editor's suggestion), and the notes which follow are for his benefit. I do not propose to suggest how his bit of rock garden should be constructed: that is a different question; but the plants which I shall suggest are all easy hardy perennials which will grow wherever they are given a fair chance. And a fair chance chiefly means a reasonable amount of sunlight and a well drained soil.



A ROCK PLANT OF REAL MERIT, VIOLA GRACILIS ALBA.

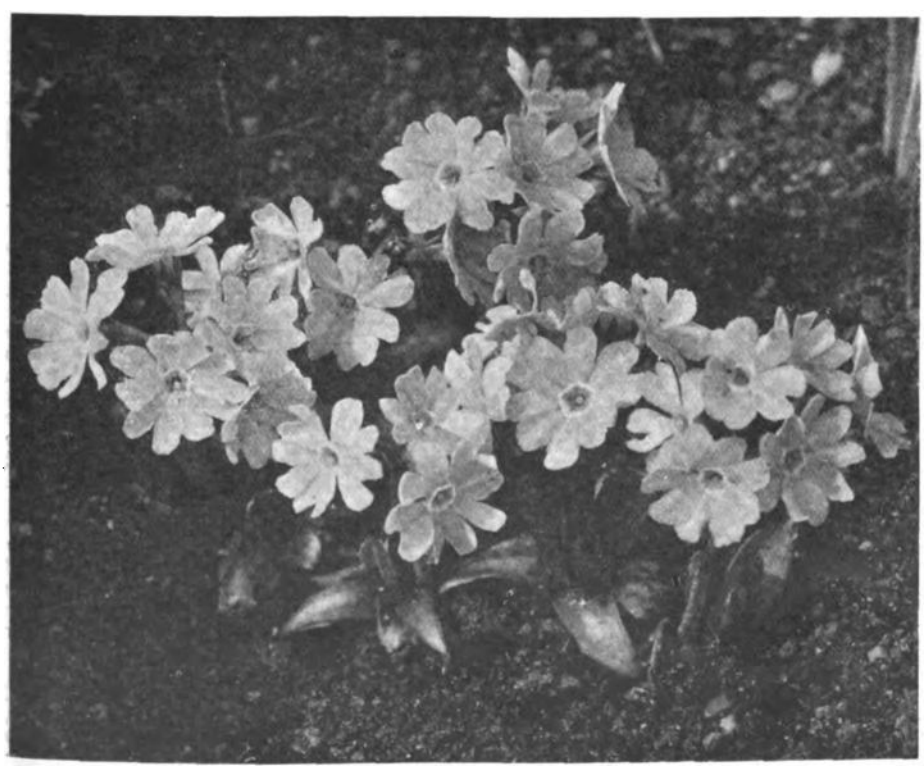
How to Select Your Plants.

Now, what kinds of plants are the most suitable and most desirable for the very small rock garden? The choice is determined by (1) size: they must not grow inconveniently large, or be so small as to be insignificant; (2) constitution: they must not be difficult to grow, whether on account of tenderness, special requirements or sheer cussedness; and (3) attractiveness: they must be bright and pleasing, whether by reason of flower or foliage or, better still, of both. Perhaps the remainder of the first instalment of these notes can best be devoted to pointing out a few of the plants which are *not* suitable. Among the rock garden plants which would soon become rather large are some of the pinks, especially the many garden varieties (many of the *species* are quite small and neat). Then the candytufts, iberis, form clumps which would ultimately be quite too large for our purpose; and the same applies to the more vigorous mossy saxifrages and aubrietias. That common but excellent rock plant, Arabis albida, had better give place to choicer and less rampant things. But more to be avoided are the many rock plants which creep, sending out roots as they run on or below the ground; for most of these spread with great rapidity and are often difficult or almost impossible to eradicate. Many of them are lovely, but in the very small rock garden they are sure to smother their neighbours, and there are plenty of lovely things one can grow instead of them. These dangerous plants include all the periwinkles, epimediums, acænas and cotulas, the woodruff (Asperula odorata), many of the geraniums and hawkweeds (hieracium), the crosswort (Crucianella stylosa), the waldsteinias, Coronilla varia, the New Zealand epilobiums (E. Hectori, etc.), Helxine Solierolii, the creeping kinds of toadflax (Linarias repens, pallida, hepaticæfolia), and of sedums (SS. reflexum, rupestre, anopetalum, sexangulare, album), Zauschneria californica, and so on.

As to plants which are in one way or another rather difficult, and are better left alone till some experience in planting and tending has been gained, the following may be suggested: Soldanellas, raoulias, schizocodon, conandron, lewisias, the smaller androsaces, and most of the primulas and gentians. These look very tempting at the shows, where one often sees abundance of flourishing plants *grown by expert nurserymen*; but they are mostly rather dear and difficult, and the beginner will do better to stick for a while to easier things. But not for ever. Never venture, never win.

R. LLOYD PRAEGER.

(To be continued.)



THE DAINTY PRIMULA ROSEA, ONE OF THE MOST ATTRACTIVE OF ITS RACE AND ONE OF THE EASIEST TO GROW.

An Attractive Rock Garden Violet.

THERE is no more delightful little plant for the rockery than the lovely Viola gracilis, with the habit and vigour of V. cornuta but much neater in its blossoms and richer in its colour. It does not ask for any particular care in cultivation, but grows readily in a light and open soil, which is enriched with manure. It can be propagated by cuttings like an ordinary bedding pansy. The white form alba is particularly charming as are also its various velvet purple varieties.

Primula rosea.

GARDENERS of all kinds must feel that there is an immense satisfaction in the fact that one of the loveliest of primulas ever grown is one of the easiest. In P. rosea, a Himalayan alpine, we have a species which will thrive in shallow water, in bog or in any

Digitized by Google

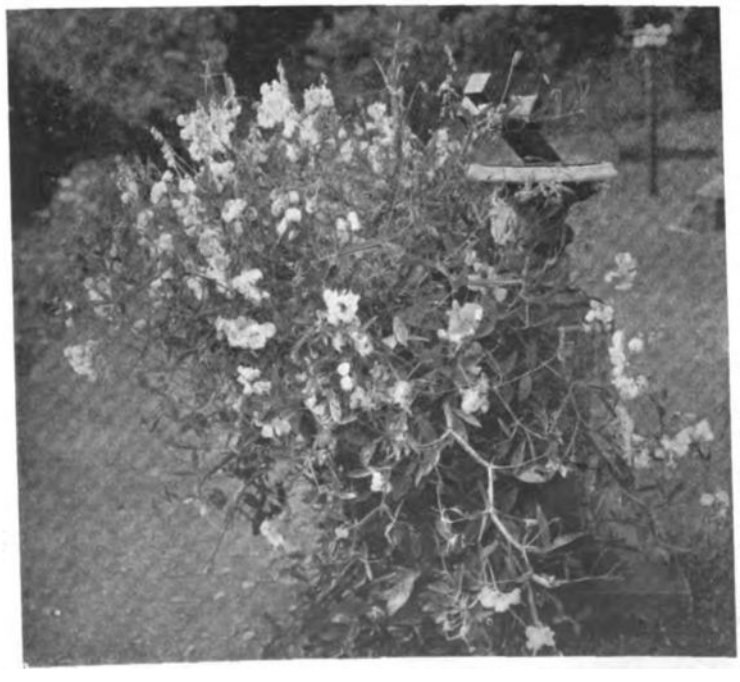
cool border or rock garden soil that is enriched and rendered more retentive of moisture by the addition of a little old cow manure. It is, moreover, not particular as to aspect, while in hardiness and vigour it can rival our own common primroses. P. rosea makes a moderate sized tuft of its narrow, glossy leaves. These almost entirely disappear in winter, but at the first peep of spring the crown becomes studded with those brilliant knobs of ruby crimson which precede the uprising flower stems. The latter grow to some 6ins. or more in height and terminate in a cluster of large yellow-eyed blossoms of a most entrancing shade of rosy carmine and these prevail for many weeks. Few plants, especially waterside plants, are so welcome and so cheerful in early spring as the lovely blooms of P. rosea, and I do not think they ever look so delightful as when associated with the cool, clean blue of Omphalodes cappadocica. P. rosea is found in many forms, these differing in the size and shade of colouring. All are delightful, but those who desire the most brilliant will find such varieties as splendens and grandiflora superba in every way admirable. Planting may be done at any time during autumn and winter and propagation is easily effected by division, preferably during late summer. J.

SOME CLIMBERS FOR ARCHES AND PILLARS

ON the whole I think that, next to the rose—with which it is not proposed to deal in these brief notes—the clematis is the most popular climber for an ordinary garden arch, especially in its large-flowered forms. And nothing can be more effective, particularly if a white and a mauve or purple variety are planted on each side of the arch, one of either colour being of the early-flowering patens type and the other of the later lanuginosa to ensure a succession of bloom. Marcel Moser and Mrs. G. Jackman may be planted side by side, for instance, and Lord Londesborough and Mme. van Houtte or Lady Caroline Neville. Clematis montana may be grown with its reddish pink variety, but C. Flammula with its clouds of sweet-scented white blossoms looks best alone. All the members of the lonicera family are admirable for clothing arches, especially those of rather light construction. The best known is the very fragrant red and yellow Dutch honeysuckle, but L. flava is equally pretty (but not quite so hardy), and best of all is L. sempervirens with its fine scarlet trumpets. This last, however, needs a very warm and sheltered situation. The Japanese honeysuckle, L. aurea reticulata, is hardly sufficiently important to be used alone, but if the seeds of such annuals as Convolvulus major, Lathyrus sativus azureus (both blue) or a scarlet nasturtium are sown at its foot and they are allowed to climb up through the gold-spangled foliage of the honeysuckle, the effect will be charming. The half-hardy perennial Tropæolum tuberosum may be substituted for the annual nasturtium as being less likely to strangle its host, but it is a less vigorous grower.

The perennial Lathyrus latifolius will cover an arch well, the most popular varieties being Pink Beauty and White Pearl. Lathyrus rotundifolius is less well known, but its racemes of small rose red flowers are borne in the greatest profusion, and it will grow 12ft. or more in a season. Lathyrus grandiflorus, which bears very large rose-purple flowers in pairs, is seldom seen except in old gardens, but it looks exceedingly pretty if allowed to ramble over and through an ivy—say, the large-leaved Hedera Ragneriana, the quaint Dutchman's pipe, Aristolochia Sipho or one of the vines. Of these last, Vitis Coignetiæ and V. vinifera purpurea are the most desirable by reason of their rich autumnal colouring. The well known Virginia creepers, Vitis (ampelopsis) quinquefolia and V. inconstans, are too commonplace to be worth consideration, but V. Henryii and V. heterophylla are rather less hackneyed. The giant convolvulus, Calystegia sylvatica, will drape a light arch very successfully, especially if combined with its pink variety, but it is indisputably a dangerous thing to admit into a garden because of its encroaching tendencies and the thug-like way in which it will strangle its neighbours.

Among other good ornamental climbers are the actinidias, especially A. Kolomikta with white flowers and A. arguta with yellow. These are hardy, but like a good rich but not heavy soil. Then there are Polygonum baldschuanicum, which has feathery, pinky white flowers borne in immense numbers; Passiflora cœrulea and its white variety Constance Elliott, Solanum jasminoides (neither this nor the passion flower is hardy except in a very mild district), and, of course, Wistarias chinensis and multijuga, the beauty of which is familiar to all. Solanum crispum, the purple flowers of which are so like those of the potato, is generally grown as a wall shrub, but it can be easily trained over an arch. It is quite hardy and will bloom more or less throughout the whole summer, but it must be cut hard back after flowering. Forsythia suspensa (the golden bell tree), Garrya elliptica and Kerria japonica can all be used similarly, but these must be pruned sparingly and with discretion. The single kerria is far less widely grown than its double variety, but it is really prettier both as to habit of growth and flower, its only fault being the shortness of its blooming season. SOMERSET.



A FINE PLANT OF THE EVERLASTING PEA, LATHYRUS LATIFOLIUS.

CLEMATIS MRS. JACKMAN GROWING OVER AN ARCH.

Eradicating Pests in Arches and Pergolas.

ONE great objection to arches, poles, pergolas and such-like things in the open garden is the tendency they have to form ideal winter quarters for many different kinds of pests. Every crack, every piece of loosened bark, every open joint may be the winter quarters of pests of some kind in a dormant state. To make such erections quite safe it is always a good plan to wash them down every autumn or winter. First of all, however, roses or other shrubs should be loosened and all bark which can come away readily ought to be taken off and burned. A good erection may then be worthy of a coat of varnish or paint, which not only kills all pests but prevents them returning there again. A wood preservative like creosote or a similar proprietary liquid may be used. Care in such a case is necessary not to allow the caustic fluid to drip over shrubs or plants near at hand, nor may the shrub itself be retied in position until some time has elapsed. Failing treatment by either of the above methods, a useful liquid to use is paraffin oil or, even better, a mixture of paraffin oil and petrol. This liquid, painted on with a brush, penetrates into all interstices and effectively kills pests. CLYDESDALE.

THE FLOWER GARDEN

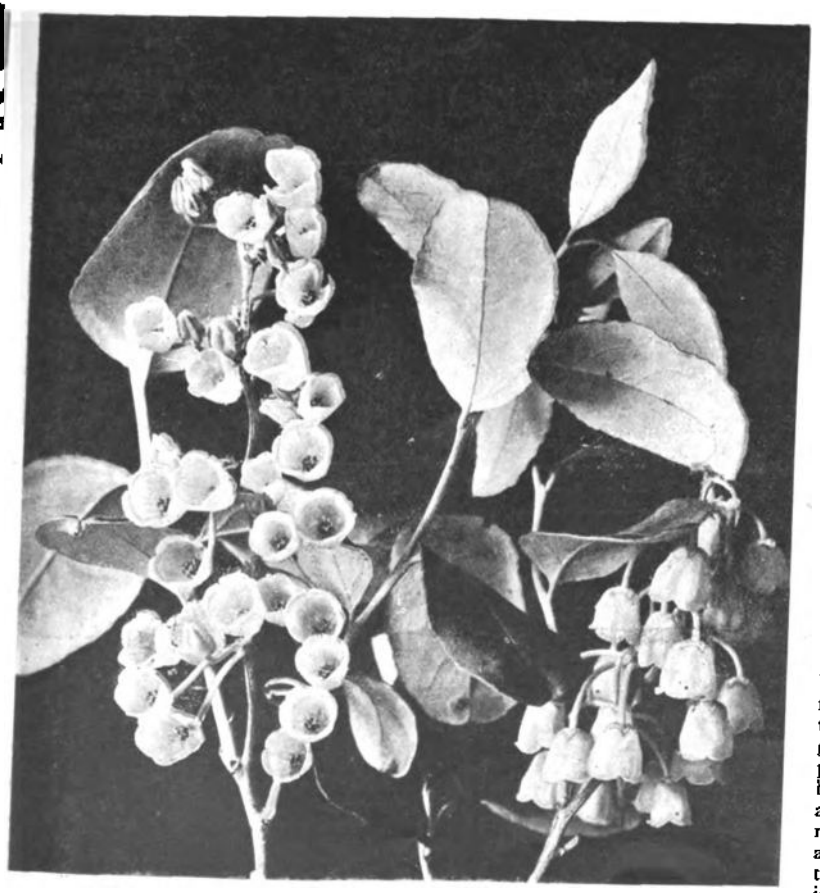
A Climbing Knot-weed.

THE beautiful Polygonum baldschuanicum is, for some reason or other—perhaps it is handicapped by its terrific name!—less often seen than it deserves. It is rather slow starting into growth after planting, but, once established, it will go ahead rapidly and reach a great height in a very short time. It is not as suitable for an arch or pole as for a pergola or veranda; but to see it at its best it should be allowed to climb over some useless tree. In the writer's garden it was planted some few years back at the foot of a tall pear tree too ancient to bear fruit, and this it has now completely draped, hanging in festoons from the topmost branches. When covered with the feathery, pinkish white flowers, which it bears in immense profusion, it is a lovely sight. It is said to be September-blooming, but I find it begins to flower about the end of July and continues until the early autumn. I believe it is usually propagated by grafting upon cuttings of its own roots, but it can be also grown from seed or from layers quite easily.—R. E. H.

A Beautiful Free-flowering Shrub.

THIS beautiful and free-flowering American shrub is still seldom seen in gardens, although the type was introduced to this country in 1801 under the name of Andromeda cassinifolia. The variety pulverulenta is an improvement on Z. speciosa; it flowers more freely, and the individual blooms are larger, while its young stems and foliage are powdered with white. The glaucous leaves render it quite distinct from the type.

The plant under notice is nearly sub-evergreen, and will attain a height of 4ft. to 5ft. It is a lovely shrub and, owing to its white, drooping flowers, is often referred to as the lily of the valley bush, a description which fits it admirably. The flowers are produced in axillary clusters on the previous year's wood, and the shrub is usually at its best in late June or early July. This is a shrub that should find a home in every garden where there is space, and it should be borne in mind that peaty soil is not necessary, but is advisable, so see that the loam is made light and is well drained. Leaf-mould can be added with advantage.



THE BEAUTIFUL WHITE BELLS OF ZENOBIA PULVERULENTA.

A Useful Wall Plant.

THERE is no more useful and beautiful flowering shrub for walls or corners of buildings than the ceanothus. This shrub is much hardier than is generally supposed, and we have used it with success where roses and other climbers have failed owing to cold aspect and other drawbacks. The plant in the accompanying illustration is the variety Gloire de Versailles, which is not usually planted on walls. This variety, however, is most suitable, especially if given a corner site where it has a little more than ordinary space. The photograph was taken late in October, and shows the plant flowering for the third time this year; in fact, this particular corner of the house (aspect south-east) has been a haze of lovely lavender blue almost continuously throughout the summer. I prune it back in the spring, and it is then allowed to grow freely during the remainder of the year. All the varieties of ceanothus do well and grow very freely in seaside districts.—H. JENKINS.

CEANOTHUS GLOIRE DE VERSAILLES AS A CORNER WALL SHRUB.

The Culture of Lily of the Valley.

ONE of the most delightful corners of the garden during the spring months is the lily of the valley bed, but, alas! in how many places are the plants seen to be dwindling, while the flowers are very mediocre, hence this note of warning and advice.

When a bed or border of this favourite flower is left undisturbed for a number of years, the quality and quantity of the spikes deteriorate. Directly this is noticed, say, every three or four years, a bed should be lifted, the plants divided and replanted. At the same time a portion of the flowering crowns could be selected for pot culture. By growing the plants in borders with aspects north, east and west the flowering period is prolonged. The beds should be dug deeply, at the same time incorporating decayed manure and leaf-mould. When the ground has been made firm, replanting can be done. Clumps of five or six crowns are placed 6ins. apart, and then no further disturbance will be needed for several years. Old beds may be mulched with rotten manure or leaf-mould.

Many will prefer the old or smaller variety of lily of the valley, while others may enjoy that known as Fortin's. This is a giant variety, no doubt the finest form of all. The bells are pure white and extra large, while the stalks are also stout and a good length. Planting of the crowns should take place when the ground is dry enough for such work to be performed.

An Attractive Dwarf Shrub.

ONE frequently thinks that the value of shrubs of dwarf growth is not too well recognised by a great number of those who possess small gardens, included in which are rockeries for the cultivation of alpine plants. There is no doubt that the presence of a greater number of these little shrubs would increase the beauty and interest of the garden. One small shrub which is not by any means too plentiful is Bryanthus erectus, said to be a bigeneric hybrid raised in Edinburgh. It is only from 8ins. to 10ins. high when fully grown and is most attractive on account of its neat foliage and its pinkish flowers. It is by no means troublesome to cultivate, and the stock prescription of a soil such as suits what are called "American plants" will please it. A nice sandy loam, with the addition of some peat, is appreciated by this little shrub, which thrives quite well in sun. It ought not to suffer from drought in dry weather, and where there is a danger of this, a thorough soaking of clear water should be administered in good time.

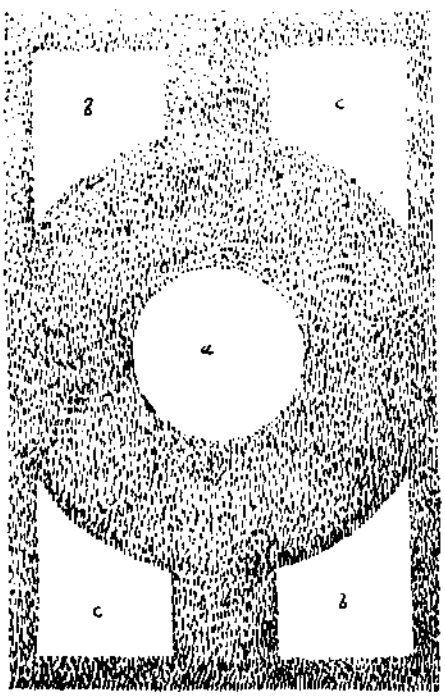
Bryanthus erectus is by no means plentiful in nurseries, but is obtainable from some. It is best procured in pots and planted out in spring or autumn, preferably the former, although, if in pots, it may be removed

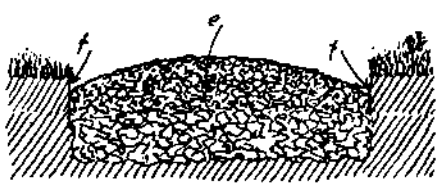
Digitized by Google

from these at any time without breaking the ball of soil.

Making Flower Beds on a New Lawn.

SOME lovers of flower gardens form the new beds on their new lawns before they sow the seeds where seed-sowing is preferred to turfing. This is not advisable,





as it can only be carried out at all satisfactorily when boards or iron hoops are used to retain the soil edge firm; and, furthermore, it is a difficult matter to obtain a well balanced design where geometrical designs are required. Where turves are laid there need not be any trouble with the edges nor with the effort to obtain a true design, as the edges of the new turves can be cut as freely and as truly as when cutting out beds on an established lawn. The whole space need not be covered with the new turves, but the latter should be laid well covering the edges of each proposed bed, and underneath this particular band of turves the soil should be well trodden down so that, when the edging iron is inserted, a clean cut will result, leaving a firm, straight edge and not one that caves in like the sides of a brook. A simple design for flower-beds on a small lawn is shown at *a*, *b*, *b*, *c*, *c*, respectively. A rule, a straight-edge, handy plank, a line and several pegs will enable the workman to mark out the respective beds, whether one isolated or a number of them. At *d* the soil is shown deeply dug; at *e* finer soil forms the planting portion and the proper height of the soil of the bed above the seed-raised grass. It is at *f*, *f*, that difficulties may arise, and to prevent the edges falling inwards the soil of the border should be almost as high up as to touch the grass. The following year a firmer edge can be made. Do not place any soil from a bed on the young grass but in a wheel-barrow.

Two Choice Anchusas.

THE anchusas belong to the borage family, and two forms of A. italica call for notice, namely, Opal and Dropmore. The former has soft sky blue flowers, and the latter flowers of the finest blue. Both are admirable plants for the herbaceous border where a bold mass of a subject 4ft. to 5ft. high is needed. To keep up a supply of plants a few should be propagated annually, and the best and usual method is root cuttings. At this season the borders are usually dug over, and old roots of anchusa which bloomed freely this last season may be lifted and the thong-like roots retained. These are cut into 4in. to 6in. lengths, and are then placed thickly in boxes of light sandy soil for the winter. If a cold frame is available, the box can be stood inside, otherwise it should be afforded a sheltered position from excessive rain. In the spring crowns and growths will have formed, when the cuttings are transferred to their flowering quarters.

Anchusas can be raised from seeds, but root cuttings form the only means of perpetuating named varieties. Seedlings vary considerably in colour.

SOME BORDER CHRYSANTHEMUMS WORTH GROWING

WITHOUT doubt the chrysanthemum is one of the most popular flowers of autumn. It is perfectly hardy and its cultivation is a comparatively simple matter.

The old idea of treating these plants as ordinary herbaceous perennials ought not to be practised. Formerly the plants were left for two or three years, then considered done, new cuttings taken or new plants bought. The new and better way is to take up the old plants from which cuttings are required and plant them in a frame in autumn. Throughout the winter air is given on every favourable day and in early spring the plants are top-dressed with sandy soil. When the new shoots are 2ins. long they may be taken as cuttings and if the frame is kept closed and the soil moist, they soon root and after being hardened off, may be planted out of doors —some time in June.

There are a few amateurs who still treat border chrysanthemums in the old way and complain because they have no greenhouse in which to grow the large blooming late varieties. Large blooms may be grown outside, however, if just a little more care and attention are given to cultivation. It is very disappointing to have good blooms cut down by early frosts in autumn and for this reason a border out of the way, that is a portion where some light framework covered with muslin may be fixed without making the front garden look unsightly, should be chosen. Here you may grow many up-to-date varieties. There are any number of varieties which can be grown by the novice and a selection can easily be made from trade catalogues.

Varieties.

Those who desire quantities of bloom for table decoration could have nothing better than September White or Shirley Blush. Both are wonderful croppers and the fact that the former is grown for market proves its worth as a white for cutting. Shirley Blush comes almost pure white on many soils, but is a good flower bearing huge crops of bloom. It does best disbudded. This is a plant of comparatively recent introduction. Those who grow border chrysanthemums for cut bloom should also grow Harvester. Deep yellow in colour, heavily shaded with orange bronze, it bears huge crops of beautiful blooms. Another variety of recent introduction is Bronze Early Buttercup, a large flower of good proportions, rich shade of bronze chestnut, with golden reverse; gives good crops, from twelve to eighteen blooms per plant. Wembley is another newer variety. Dark crimson in colour, with broad reflexing petals; by disbudding huge flowers can be obtained.

Other early varieties are Shirley Bronze and Sunburst; these are also new. This list is by no means complete and as the selection of plants is really a matter of personal taste, the gardener must consult the growers' lists for varieties. The varieties mentioned may be easily grown by the gardener who has had little experience of chrysanthemum growing. The object of these notes is to point out to those who do not already know, that so long as one is content to have early chrysanthemums—from August onwards—he can produce blooms that will vie with any grown indoors later on. The early chrysanthemum comes into bloom just when the evenings begin to come dark and when flowers outdoors are scarce and are then much appreciated for table decoration. I do not disparage inside grown chrysanthemums; I grow more than the border varieties; lack of space outdoors is the reason. Those who have no greenhouse will be well advised to carry out the suggestions given above and provide some light protection from frost to prolong the bloom outdoors. It may seem venturesome to write about these flowers now,

SEPTEMBER WHITE, A BEAUTIFUL VARIETY FOR TABLE DECORATION.

but "gardening" consists of anticipation, so make your choice now of what you will grow next autumn.

No mention has been made of single varieties, but the lists give plenty of suitable kinds, Shrapnel, orange terra cotta, is fairly new. Older varieties are to be found in the growers' lists.

THE BUSY MAN'S PAGE

Rotation in the Flower Garden.

MOST people give consideration to the question of rotation in connection with vegetable crops. It should be realised that a similar system is highly desirable also where flowering plants are concerned. Roughly speaking, no position should contain the same kind of plant more often than once in four years. Even in the case of herbaceous borders, which do not admit of a regular rotation, some kind of scheme should be adopted and always the results are worth while. It will be found that the plants benefit very much by a change of position and, if the roots are lifted every third year, the soil is not exhausted to the extent which is often the case. The removal may simply be a mere change of site for the individual plants; for example, the Michaelmas daisies might change places with the sunflowers. In this way the removal of all the plants to another border is avoided. Rose bushes, too, are improved by being transplanted into a new position. Where a fresh situation is not available, re-set the bushes in the same hole with plenty of fresh, rich compost. Of course, in the case of woody plants of slow growth, any system of rotation must be extended over a long period, as, in many cases, the specimens take some years to settle down.

Seasonable Garden Work.

THE root pruning of fruit trees that have been making gross growth should be completed and the planting of young trees not done in November deferred to February or early March. Pruning of wall, standard and bush trees should be undertaken, also of black and red currants, as time admits. If raspberries have not been seen to, old canes and weaklings should be cut out, regulating vigorous canes to five or six per root. Chrysanthemum stems may now be cut down. In frosty weather manure should be wheeled on to vacant ground and room made for it in portions to be dug. Digging should be commenced whenever the ground is in favourable condition, all leaves should be swept up and dug in or placed in a heap to decay, if required to be used for potting. A few stools of Christmas roses should be lifted and placed in boxes or pots and taken inside, where there is a greenhouse. Frames that contain bedding out plants, pentstemons, calceolarias, violas, etc., should be given free ventilation in mild weather.

Repairing Broken Pots.

POTS of good size are rather expensive and it is a very wasteful habit to throw these on one side should they become broken. When, as usually happens, the pot is only broken into two pieces, it may be quite well repaired. Get some cement and silver sand and mix these materials, using equal quantities of each with water. Do not make the preparation too slack. Slightly damp the broken surface of the pot and then apply a thin layer of cement. Press the parts well together and scrape away any surplus cement with a knife. The cement sets quickly and the pot will be ready for use in a few hours.

Enriching Soil near Evergreens.

FEW amateurs realise the extent to which evergreen shrubs will impoverish the soil. It is often noticed that plants growing in proximity to these shrubs show a progressive decline in vigour, and this is due to the fact that they are simply being starved out. The effect is commonly to be seen in the case of a bed of lilies of the valley which, in course of time, may give such poor results that the owner concludes that the position does not suit them. The bad state of the soil is the sole cause of the trouble and this may be easily remedied. Open up holes over the surface of the ground, and into these work well decayed manure. Another way is to scatter over the soil a layer of leaves, lightly covering these with soil of good quality. If they can be obtained, oak leaves are the best for this purpose, as they carry fewer pests than other kinds of foliage, but almost any leaves from deciduous trees will be better than nothing.

Christmas Roses.

THE beautiful flowers of the Christmas rose are often largely spoiled through being splashed with mud during rainy weather. The common plan of protecting the plants with lights or sheets of glass is not necessary if the ground in the proximity of the specimens is covered with straw manure. This will entirely prevent the throwing back of those mud spots which sully the whiteness of the blooms. The manure, also, has a wholesome and stimulating effect on the plants, which encourages them to develop their flowers freely.

CHRISTMAS ROSES SHOULD BE PROTECTED WITH A LAYER OF STRAWY MANURE ROUND THE PLANTS TO KEEP THE FLOWERS WHITE AND PURE.

Roses as Garden Screens.

THREE years ago a new garden was started and the necessity for evergreen screens presented itself. It was decided to try Albéric Barbier roses grown on trellis.

By the end of the first year the screens were lightly covered. This year half the growth has had to be cut away, so thick have the roses become.

The situation is clay soil and very exposed. The growth has been most satisfactory, the flowering starting early and continuing throughout the year, the profusion of beautiful yellow-white roses on the rich varnished green foliage making a charming picture. Curiously, the aphis affects this plant very little. This summer, when the neighbouring American Pillars and others were brown with an aphis attack, the Albéric Barbiers were so little affected as to leave the leaf unspoiled.

Usually this rose is grown on a wall, and it was with some doubts that it was planted on a trellis in the open in this instance. The result has been most gratifying. As an evergreen for winter screens it has been a success.

When You Order Seeds and Plants.

SEEDS, plants and bushes, etc., should be selected with care. Take into consideration the character of your soil when ordering seeds and fertilisers. Send in your orders early. Delay in ordering may result in a serious delay in getting the seeds sown. Do not choose the cheapest of seeds, nor of anything else for the garden. From well tested seeds you should have over 95 per cent. that will germinate and grow. You can sow more thinly and with confidence when using good seeds. That means a saving, in fact, for ½oz. of good seed may cover more ground than 1 oz. of a less satisfactory kind.

When your seeds arrive, do not allow them to become bad, either by keeping them in a damp place or in a drying heat. Plants, also, should be taken care of when they arrive. Do not allow them to lie in any odd place, with roots exposed, but lay them at once in fresh soil. A still better plan would be to set out the plants in a vacant space of ground in such a way that they could be lifted (when required for planting), with a nice ball of soil at their roots. Fruit trees and bushes should also be laid in a shallow trench with roots well covered with sandy soil until they can be planted.

Moss on Paths.

DURING damp weather moss is very likely to appear on paths, especially where the walks are somewhat shaded. One of the simplest and most effective ways of dealing with the moss is to brush it away, if it is not firmly established, with a stubby besom and afterwards give the path a good rolling. In this way a path may be kept free from moss and, in addition, the development of weed seedlings is kept down.

A Cold Weather Hint.

WHEN doing work out of doors with a hammer and nails one's hands often get uncomfortably cold. Here is a little idea which will help a lot on such occasions. Put the nails to be used in a tin canister and then stand this in an oven for a while. When the tin and nails are well heated, take them out of doors. The warm nails wil prevent the fingers from getting numb.

Digitized by Google

PLANTS FOR GROWING UNDER TREES

Many gardeners are occasionally in doubt what to plant under trees and other shady places. In the following article a selection of both useful and attractive plants will be found. They will grow in most shady places except under beech trees.

THE average amateur who wishes to brighten up the shade of trees with flowering and other plants could hardly do better than start away with a few ferns. These are always delightful, and they form an admirable background for most subjects. I need scarcely enter into the question of kinds, but where the space is limited such good sorts as Adiantum pedatum, Klondike variety, the oak-fern, harts-tongue, Blechnum spicant, Onoclea sensibilis and the Ostrich-feather fern (Struthiopteris germanica) should be among the chosen.

Grouped in with the above I can recommend the single-flowered orange form of the Welsh poppy, the lemon yellow type plant being safer in larger areas and the wild garden. Where there is a little sunlight, that elegant woodlander, Aquilegia formosa, should be introduced; and another columbine for which I have a deep regard in such conditions is the old English large-flowered white. Scillas one must always have, both S. nutans (the plant we call "blue-bells" when we wish to make Scotsmen angry) and S. hispanica in pure white, rose and various shades of blue-purple. These do very well in quite sunless places, and as they are practically over before the ferns are fully developed, they may be grouped with them. As an alternative you may plant, more or less together, any of these scillas and Solomon's Seal.

Primroses, as we all know do not ask much sun, and these, in their various colours—not forgetting the lovely blues, delight in the company of deciduous trees. So does Anemone Hepatica, and where will you find a more charming plant for giving bright bouquets of blue, white and rose among mossy rocks or stumps, than these?, The autumn-flowering cyclamens make excellent companion plants for the foregoing and, for that matter, may be worked in among such anemones as those of the nemorosa class: A. trifolia, a dainty alpine version of our own windflower; A. apennina, and others of their delectable race.

The Wood-Sorrels.

There is no more bewitching little plant for shady woodland retreats than the carmine rose form of our own wood-sorrel, and once this has been established it will naturalise freely. Oxalis oregana, which is a good deal larger, is also pink and good, and so is O. adenophylla and before leaving these smaller things I must not forget to mention the dog's tooth violets, snowdrops, spring and autumn crocuses, daffodils, ornithogalums and colchicums. But bulbous plants which do well in shade which is not too dense are so many that a special article might be allotted to them alone. So, to pass on, let me remind the reader of the milk white rays of Sanguinaria canadensis,

THERE ARE FEW MORE CHARMING PLANTS FOR A SHADY SITUATION UNDER TREES THAN OUR WOOD SORRELS. THIS IS OXALIS ADENOPHYLLA.

an ideal woodland plant; let me suggest some patches of Omphalodes cappadocica and verna, and of their relations, the intensely blue Anchusa myosotidiflora and the chastely elegant Borago laxiflora, which loves to swing its opal bells among ferns and woodland herbage.

The best of the lungworts must be included, for they will flower with the winter aconites, and Pulmonaria azurea in its finest forms is a really strong, clear blue. Gentiana asclepiadea, so easily raised from seed and always to be included in a list of woodland plants, will give us a variety of colours from deepest indigo to palest azure and white during the later months of the season. Lily of the valley must not be forgotten here; and then there are the cimicifugas, of which C. simplex is one of the best of smaller stature for our purpose here. The trilliums will do in the densest shade where the soil is rich, free and cool, and in addition to the Christmas rose (Helleborus niger) there are many hellebores, especially in the orientalis section, which are first-rate shade subjects for growing with ferns and other rather bolder things. White foxgloves always look delightful under such conditions, and few who have not tried it realise how well Campanula grandis looks in thin woodland shade. C. lactiflora, especially the selected varieties which are not too tall, is also most attractive, this being a native of some of our densest woods.

Dicentra formosa and D. eximia should both be grown in woodland shade, their elegant glaucous leafage being followed by hyacinthine heads of purple and rose. Corydalis cava, more especially the white form, C. cava alba, which looks like a Roman hyacinth and smells nearly as sweet, I must always have in some shady nook where it will gleam forth every dawning year, early among the earliest. The foam flower, Tiarella cordifolia, is quite indispensable, its wine tints of autumn being by no means the least of its pretty

THE WILLOW GENTIAN, G. ASCLEPIADEA, IS ALWAYS TO BE INCLUDED IN A LIST OF WOODLAND PLANTS.

Digitized by Google

attributes. Galax aphylla will enjoy any cool, leafy spot, put up snow white spikes in early summer and embellish the rich green of its round glossy leaves with crimson throughout the dead months. All the periwinkles are useful woodland shade plants, care being taken with the placing of Vinca major, which is apt to be rather too robust in some soils. V. difformis for autumn-spring flowering is very charming, and the little fellows (V. minor) in their infinite variety thoroughly appreciate the light shade of deciduous trees and flower from February to June. Under similar trees which are fairly tall Erica carnea has often proved an excellent subject. It makes drifts of rosy carmine under some of my old oaks from December to May. Indeed, I know of only one other shrub of similar stature which is equally pleasing, though it cannot rival the heather in brilliance, and that is Polygala chamæbuxus purpurea.

THE LOOSE STARRY SPRAYS OF TIARELLA CORDIFOLIA.

This comely little alpine milkwort, with its myrtle green, box-like leaves, is hardly ever out of flower. It will do in deeper shade than the heath, and throughout the spring and early summer, and again in autumn, its beautiful green carpet is adorned with a galaxy of golden keeled, purple-winged butterfly flowers.

This list might be much extended, but, having been offered a few suggestions, the reader should be able to gather something of the line to take in making his selection. I will only add that few plants will do much good if put directly into virgin woodland soil. The latter is often impoverished and full of roots. Some cultivation will, therefore, have to be carried out before planting, the extent to which this is necessary being decided by the nature of the soil. Trenching is, of course, out of the question, but by deeply digging the parts to be planted, loosening the subsoil and adding some old manure or vegetable compost, a most uncongenial soil can easily be made suitable for any of the subjects mentioned here.

DECEMBER IN THE GREENHOUSE

A Note on Bulbs Growing in Pots and Bowls.

IT may not be out of place, to pass along a few hints to those in whose hands the culture of bulbs is not always an unqualified success. First, as to moisture. Hyacinth roots and, indeed, all bulb roots demand that there shall be no lack of moisture, but it must not be sour. Remember that in all bulbs the leaves and all of the flowers down to the last pollen anthers are all fully formed in every detail within the bulbs before you plant them and a constant supply of pure moisture, warmth and light in due season is all that is necessary to produce the flower spike and leaves. With bulbs in pots or bowls we are not interested in the *growth* and increase of the roots for future years. If you like to buy coconut fibre decorated with mother-o'-pearl or oyster shell, there is no objection to the mixture, but it does not in itself provide any food or nourishment to the bulb, nor is it necessary to do so. The function of the fibre is the purely mechanical one of supporting the bulb in position and maintaining by its spongelike nature a supply of moisture and oxygen. Well drained soil, moss, sand or gravel perform the same function and are equally suitable so long as means are provided to keep the moisture from going sour or stale. Sourness can be avoided by adding a little charcoal, which has the property of absorbing the harmful humours.

Hyacinths in the Dark.

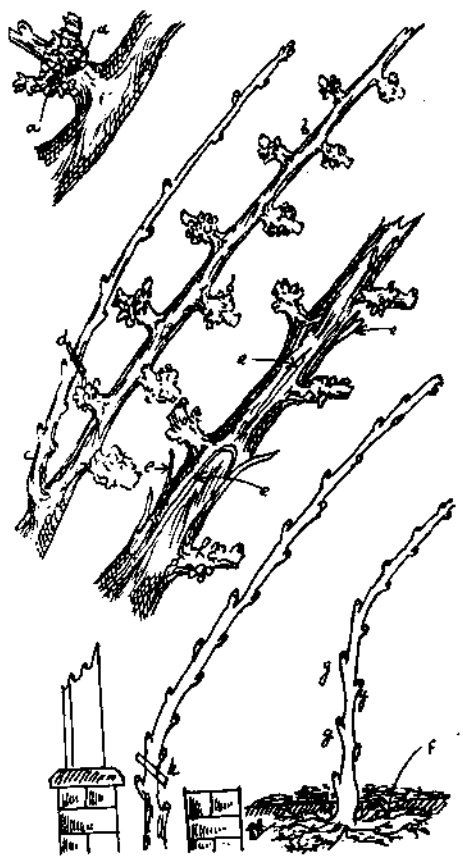
A common failing is to bring hyacinths out of the dark too soon. Everything depends on the extent of the root action, which must be well advanced to ensure success. The point to make sure of, before bringing the bulb to the light, *is that the flower spike is out of the bulb.* Never mind how many days or weeks it has been in the dark. When the bulb first begins to grow in the dark a white triangular spike forms on the top. This is the time *to leave it alone*, not to bring it out into the light. If you are in too great a hurry the result will be that the flower spike will remain in the bulb or at least be no better than a squat and misshapen dwarf. This result may also be caused by swamping the bulb with water or allowing the roots to become dry. The bulb should remain in the dark until the spike is at least 2½ins. to 3½ins. long, when a distinct fattening will be noticeable in its upper portion and there will be a thinner neck formed at the lower portion close to the bulb. This indicates that the flower has come out of the bulb and the pot may now be removed to the light in safety.

Tulips in Pots.

Tulips are not easy subjects for pots, but best results will follow if the following rules are borne in mind. All tulips in pots must be allowed to root well in cool quarters. Then bear in mind the nature of your subjects. There are very many kinds of tulips. The Duc van Thol and *some* other early varieties are naturally *very* dwarf. Therefore, in order to get good results you must (after they are well rooted and before bringing them to the light), subject them to *top* heat in order to draw up the top. This can be done in a warm, dark cupboard and they should be kept there until you can see the colour of the flower in the bud. The leaves will be yellow; never mind that. At this stage bring them right out into the light—no half and half measures or your plants will become spindly weaklings. Now, Darwin tulips—like Clara Butt, Wm. Copland, Pride of Haarlem, and Farncombe Sanders, etc.—are naturally very tall and if you follow this treatment you will be fairly sure to ruin them. The object will be to keep the top growth short and so, in order to get them early, they must have warmth at the roots and all possible light and air overhead right from the start. In an unheated greenhouse in full light they will flower in early April. With bottom heat they can, with care and skill in ventilation, be brought into flower in early February. To attempt to grow tulips in pots in an ordinary living room is to court failure. Daffodils, on the other hand, are easy subjects. Get them well rooted first in the cool—this is the essential part—then bring them within the window of the living room close to the light and turn them round to the light a every day as they grow.—H. G. LONGFORD.

Notes on Vines.

THERE are many old vines in the country; some are profitable, others are not; some can be renovated very easily, while others are not worth troubling about, young vines being much better in their places. The old vine that is not worth renovating is shown in the sketch at *a*, *a*. It will be observed



that, on the old spur, there are some round marks showing where, in years gone by, shoots were cut off. There has been so much of this cutting out of shoots that the spur has, in consequence, become blocked, as it were, and sap cannot freely flow through to sustain, much less invigorate, the shoot for the current year. So a vine of this description is not worth keeping. But one, as shown at *b*, *b*, which has not such hard, gnarled spurs, may be renovated, and to this end the cultivator should retain a nice promising basal shoot, such as is shown at *c*. The first autumn, that is, next autumn, if a young cane is retained, so in the spring of that year—1927—the young shoot should be cut off as shown at *d*. In the early part of the year all the young shoots growing from the lower spurs on the old rod must be removed while they are small. The following year—1928—the old rod should be cut out and the young one trained in its place. In the meantime, the border will require attention, too. The top soil should be removed, baring the nearest roots and some good lumpy, turfy and fibrous loam put on in its place, adding a 7in. potful of bone-meal or finely ground bones to every barrow-load.

Old rods need annual cleaning, but not a scraping. Simply remove all loose bark as shown at *e*, *e*, *e*, *e*.

Young Vines.

I like to get all vine-planting done early in January at the latest. Young vines should be allowed to start growth naturally—that is, without the aid of fire-heat, just that of a carefully ventilated vinery. The pruning of the young vines should be done at the end of December. If not pruned then, there will be danger of excessive bleeding if the cutting back is delayed, so it would be wiser to plant and not cut back at all in such cases, but, directly new shoots grow, to disbud from the point of the young rod downwards to the desired point or bud. Then the denuded portion of the rod can be cut away about midsummer or retained intact until the autumn, the young leader being tied to it during the summer. The making of the border should receive every attention; be well drained and composed of fibrous turves cut into pieces about 4ins. square, and forming a border 24ins. deep and 4ft. wide the first year. Spread out the roots as shown at *f*, and take great care of the buds or "eyes" marked *g*, *g*, *g*, as the top one should form the new leading cane, the two below being trained to right and left respectively. Cover the roots 4ins. deep. At *h*, the point to which the cane should be cut back is shown. It is opposite the bottom part of the front glass, so that the new shoots will have the benefit of the light in due course. —G. G.

Cleaning Greenhouse Plants in Mid-winter.

THERE is no better time than this for thoroughly cleaning the stems and leaves of many kinds of greenhouse plants. The latter have, mostly, completed their growth, the bark and the leaves are firmer than at any other season and are not so liable to injury. Rather stronger doses of insecticides can be applied and, furthermore, there is, as a rule, more time to use them, because there is not so much work of another kind that presses for attention. Perhaps that pest, mealy bug is the worst to get rid of and Gishurst Compound is one of the most useful of washes for the purpose of eradication. Amateurs can safely use it if they comply with the directions. Fir tree oil used to be a favourite wash of hundreds of gardeners. It was of a milky nature and grand for cleansing the leaves of the more tender greenhouse and stove plants. A small and a medium-sized sponge will be required, also a small brush with a pointed handle for use in the axils of leaves and branches. All water used should be a little warmer than the temperature of the house, and rainwater is preferable to hard well or tap—water. The plants on the roof should be dealt with first, then those trained on pillars, and the stage plants last. Before any actual cleaning of roof and pillar plants is done they should be pruned if they need it, and the prunings taken out forthwith. Established plants should be loosened from their supports so that all foreign matter can be cleared away too, and the eyes of wire pins brushed with pure paraffin, the woodwork with a stronger solution of the insecticide being used at the time.

Pot-grown plants should be laid on their sides on soft mats or sacks, then drippings

Digitized by Google

insecticide will not run down the main stem to the roots in the soil. First of all clear away any insects and foreign matter lodging in the axils of the leaves and branches, then sponge the under sides of the leaves before you clean the top side. Ornamental-leaved plants, such as crotons and dracænas, should be syringed with clear, tepid water after sponging and while the plants are still on their sides. Turn over the plants once or twice to make the cleansing thorough. Finish the work by removing the thin, top crust of soil from the pots and wash the latter. Only sponge smooth-leaved plants not any with soft, hairy surfaces like coleus plants. Scale is a troublesome pest and I advise two cleansings in the case of plants infested with it. Old brown looking scales are full of young ones and when the old ones are bruised, the young scale is spread over the branches. Directly they become dry they adhere to the bark again and in spring grow rapidly, that is why I advise two cleanings and two syringings the same day.—G. G.

Plants in Foggy Weather.

THERE is no doubt that a spell of fog, particularly that kind which is likely to be experienced in the neighbourhood of large towns, has a very harmful effect on indoor plants. The stagnant atmosphere, heavy with moisture, the total absence of sunshine and the fact that the fog is laden with smoke particles all tend to arrest the healthy development of vegetation. The results are most evident in the case of such specimens as may be coming into bloom at this season, such as pelargoniums, carnations, primulas, cinerarias, etc. Here a day or so of bad fog will cause dropping of buds so that all hope of a fine show of blossom may be shattered. Maidenhair ferns, and other ferns, will often suffer very badly indeed from the smoke-laden atmosphere. The harmful effects are seen not only on those subjects in greenhouses and frames, but are just as much in evidence in the case of house plants.

While the fog lasts a certain amount of harm seems inevitable, but a good deal may be done to mitigate the evil by careful attention to a few points. Steps should be taken to keep the fog out as much as possible, and on these occasions ventilation must practically cease. Without a doubt the less active plants are over a foggy period the more likely they are to escape injury. Thus it is a really good plan to keep the temperature rather low providing no risk from actual cold is incurred. Suspend all watering, even if this means allowing the plants to get very much on the dry side. Keep a sharp look out for any decaying parts on the specimens and remove at once. Rotting trouble, due to the attacks of minute fungi, is very likely to spread rapidly in foggy weather.

When the fog disappears everything should be done to encourage the plants to resume active growth. When the weather is mild ventilation should be free and if any additional heat is available this can be usefully employed.

WHAT OUR READERS SAY

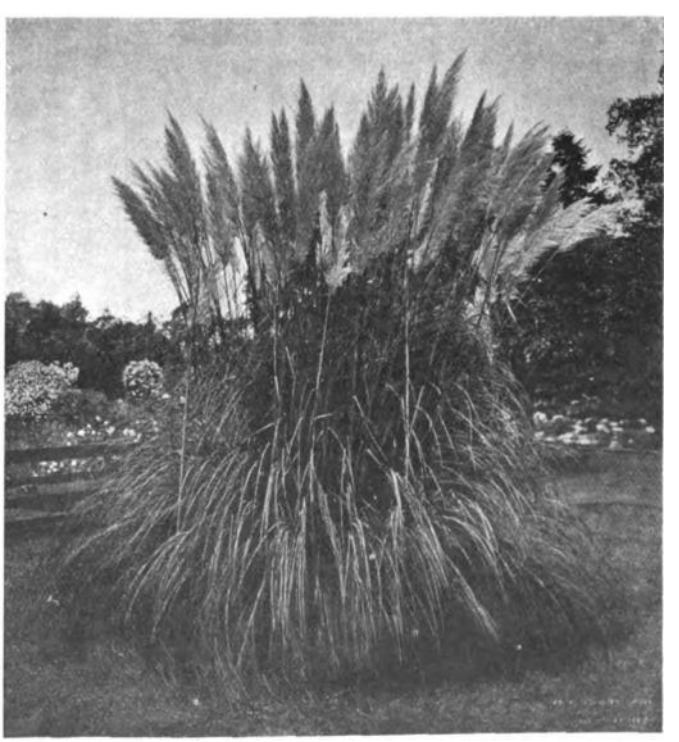
STORING APPLES ON STRAW.

SIR,—I should like to ask your correspondent, Mr. George Stuart, this question: Supposing a person has a few pounds of choice apples and wished to store them, say, till Christmas, from the time they are gathered in October. There is no fruit room, no stone or slate shelves, and certainly no messing about with clay; an ice-house or refrigerator or any kind of cooling apparatus unavailable and impossible. What is the alternative?

Surely it is a *dry shelf* covered with a thin layer of *clean straw*. And the state of mind of the person who uses anything but clean, *fresh* straw for the purpose of storing fruit is too bad for hope of redemption!—H. A. DAY.

A HANDSOME PAMPAS CLUMP.

SIR,—I do not know if your readers would be interested to see the accompanying illustration of a very fine pampas grass I have in my small garden here. It is certainly the finest specimen I myself have seen anywhere. I planted it about nine years ago when about 2ft. high. I made a hole about 3ft. to 3½ft. deep and put in about a hundredweight of manure at the bottom and then some good garden soil. Since then I have given it no more manure of any sort, but have carefully pulled out all the grass shoots which have turned brown about May. I measured it in October and the plumes, of which there were 133, measured 11ft. in height and the clump of grass was 12ft. across. The photograph was taken on October 1st this year.—C. M. WOLSELEY, *Sutton Green, nr. Guildford.*



THE GRACEFUL FEATHERY PLUMES OF PAMPAS GRASS.

ROSE MME. ALFRED CARRIERE.

SIR,—I am surprised that I can find no mention of Mme. Alfred Carrière among the many roses recommended in your paper. I planted this rose on the veranda of my east front, having learnt many years ago it was one of the few suited for this position; probably the advice was found in your columns. It is free growing, almost evergreen and a constant bloomer, and it has that rare gift, a delicious fragrance. I should give it a place in the first rank of climbing roses.—"HEDGERLEY," *Stoke Poges.*

ROSE MERMAID.

SIR,—In reply to Mrs. Anley's enquiry as to the origin and parentage of the Rose Mermaid, I may say that this rose was a hybrid of Rosa bracteata and a tea rose seedling. It was produced by Wm. Paul and Son in 1918.—G. ST. CLAIR FEILDEN.

ROSES IN SOUTH DERBYSHIRE.

SIR,—Although it is a far cry from northern Ireland to South Derbyshire, I think, perhaps, a few notes on roses in this district may be of interest. I am acquainted with practically all the varieties mentioned by Mr. Cecil M. Bailey in a recent note, and have grown most of them with more or less success.

General McArthur is a universal favourite and appears to flourish anywhere. Another rose that can be recommended is Mrs. Bryce Allen, carmine rose; the blooms are borne on strong stems and sweetly scented. The Queen Alexandra rose is freakish in colour, clashes with every other variety and produces many imperfect blooms, and, therefore, is not worth growing in a small collection.

Betty Uprichard and Mrs. Henry Morse are two of my favourites, the latter displaying remarkable lasting properties and seems to be very loath to shed its petals; it should certainly be in all rose gardens, notwithstanding its liability to mildew.

Los Angeles has taken a great hold upon rosarians in this district and has all the attributes claimed for it by the nurserymen. Another of the same variety, which can also be strongly recommended, is W. F. Dreer, which is charming for bedding or cutting.

Lady Pirrie, Chatenay, Butterfly and Ophelia are all popular, and I have yet to see a more perfectly shaped rose than the latter, although Mme. Butterfly, which is a sport from Ophelia, takes the palm for colour.

Gorgeous is rightly named and, unlike Mr. Bailey, I should include it in all collections, although I am not sure how it would fare in a town garden. I was recently looking at this rose with the rays of the setting sun falling upon it, and, involuntarily, one was constrained to describe it as gorgeous.

Harry Kirk I have grown for years, and although I appreciate its many charming qualities, the fact that it so quickly fades is, to my mind, a fault which prevents it taking high rank as a yellow; but its fragrance, together with its freedom in flowering, makes it a useful acquisition.

Mabel Morse, Christine, Golden Emblem, Florence L. Izzard, are all beautiful yellows, but the two latter are liable to die back, and they are the only two roses I have not succeeded in growing at the first attempt. So far as colour is concerned, Souvenir de Claudius Pernet is the most striking yellow rose, but it is very difficult to get a perfect bloom owing to its habit of balling badly, and it is essentially a fair-weather rose.

Clarice Goodacre, biscuit chrome, is one of the best varieties here; perfectly shaped

Digitized by Google

blooms on strong upright stems freely produced. Although it suffered severely during the winter, it has thrown up some wonderfully strong shoots with a mass of bloom.

Isobel, Irish Fireflame, Red Letter Day, K. of K. and Old Gold are all good singles or semi-singles, the first-named being especially vigorous and full of flower.

Noblesse, apricot and primrose, can be recommended and is very effective with its large-leafed foliage.

A rose that does remarkably well here is Gladys Holland, buff shaded orange-yellow, which has very large blooms of good lasting quality.

One of the most successful roses this year is the flame-coloured Independence Day, which has been prolific in blooms and a source of never-failing delight.

Lady Hillingdon, deep apricot yellow; Sunburst, cadmium yellow; Sunstar, orange edges and veined vermilion; Margaret Dickson Hamill, straw colour; Henrietta, coral salmon; Mme. E. Herriot, coral red; Donald Macdonald, orange carmine; and Mrs. Frank Bray, coppery ecru (the two latter being buttonhole roses), are all good varieties; while one of the most reliable is M. Paul Lede, with its large cinnamon pink blooms and dark shiny foliage.

Of the newer varieties nothing has pleased me more than Shot Silk, but as this is its first season with me it is too early to express a decided opinion upon it, although it gives promise of being worthy of being included in any rose garden and one that will be in great demand, its colour, bright cherry cerise over-shot with salmon orange, making it wonderfully effective. — R. C., *Alvaston, Derbyshire.*

A VEGETABLE ROOF GARDEN.

SIR,—It may be of interest to your readers to hear of a very successful and useful roof garden owned by one of my neighbours. It is a flat, lead roof and the owner devotes all his time to growing vegetables. Runner beans are grown in boxes against the walls, which are on some parts of the roof, and so well do they grow and fruit that he is able to supply his own family and the family of his son with as many beans as they wish. Round the more open sides of the roof garden tomatoes are planted and are a very profitable crop. At least 80lbs. of fruit is gathered every year. Not only are they able to eat and cook as many as they want, but a quantity of excellent tomato sauce is made for winter use. Lettuce, marrows and cabbages are also grown, some in tubs. The boxes are about 12ins. or 14ins. deep and a little broader. The soil is changed every year.

A tank in a corner, which is filled from a pipe from a tap in the house, supplies all the water needed and an old sack filled with manure is kept in the water, which, although London tap water, becomes softened and of the same temperature as the air through exposure, and this helps very much to make this roof garden so successful. Fresh vegetables are so good and if it is possible to grow them oneself, such an improvement upon those which are bought and they cost so little in comparison. I fear only a few persons have roofs upon which they could make even a small garden, but where it can be done it repays with interest all the work expended upon it and is an idea well worth adopting if space and conditions permit.—B. E. S.

THE CULTIVATION OF A SMALL GARDEN.

SIR,—In answer to the enquiries of your readers as to how much ground an amateur can cultivate successfully, I find that my garden of 25ft. by 200ft. takes all my spare time. I have a small garden in front of the house about 20ft. deep. This is surrounded by a box hedge, stone path to front door and grass path around flower-beds. This garden I plant in a formal manner with wallflowers, bulbs, etc., for a spring show, and later on with antirrhinums for a summer display. I have planted about 250 wallflowers raised from seed. The

A READER'S GARDEN WHICH HAS BEEN MOST SUCCESSFUL.

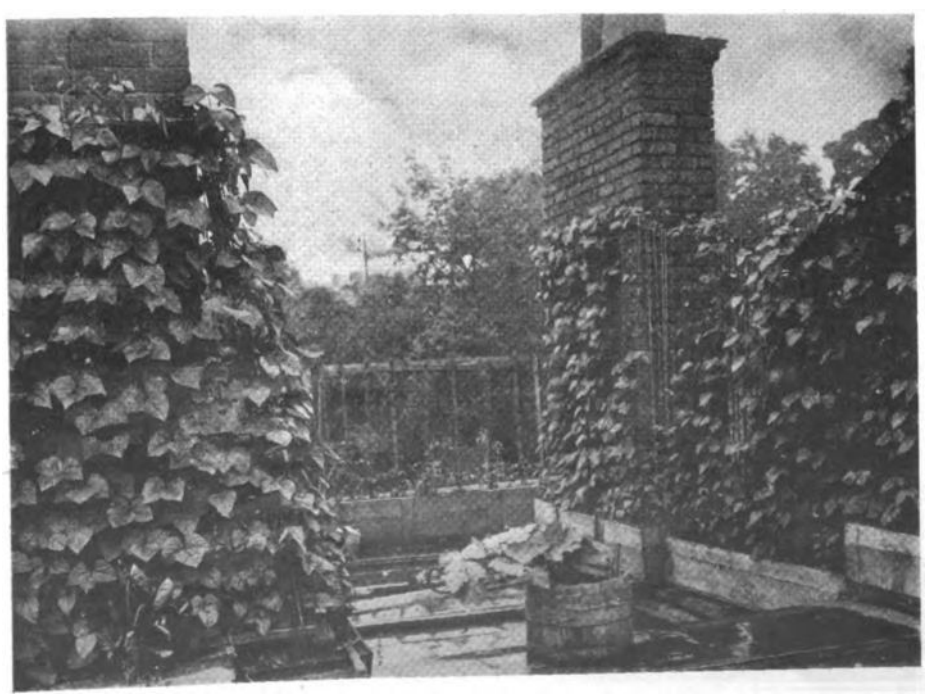
antirrhinums I usually buy from a nurseryman. The garden behind the house is about 150ft. in depth. I have a fair-sized piece of turf about 60ft. long with borders on either side for herbaceous and other plants. (I have just planted out 100 Cheiranthus Allioni grown from seed.) At the end of the grass I have a small fruit garden of cordon and bush apples, currants, raspberries and gooseberries. This takes up about 40ft. The remaining 50ft. is used for vegetables, seed bed, reserve plot for plants, etc. I have ramblers on the fences and two arches which are seen from the house. Cordon currants, cordon gooseberries and raspberries on the farther ones. I do not arrive home until 7 p.m. (3 p.m. Saturdays). I think with the variety of things I cultivate that it would be impossible to keep a very much larger garden as neat and trim as I think it should be. I enclose a photograph of my garden, taken in the summertime. This may be of interest showing what can be done with a long, narrow plot. I may add that the garden was entirely planned and made by myself out of a piece of ploughed land.—W. H. W., *Croxley Green, Herts.*

CLUB ROOT OR FINGER AND TOE.

SIR,—I was much interested in reading the note under the above heading in THE GARDEN, page 684. Perhaps my experience some years ago with land infested with slime fungus may be of interest to readers of THE GARDEN.

The ground selected for treatment was deeply dug about the first week in December and a dressing of quick-lime applied on the surface at the rate of five stones to the rod. In extreme cases double the quantity could be used without injurious effects. After lying for about six weeks the ground was lightly forked over about 3ins. deep, following which a dressing of kainit was applied at the rate of 7lb. to the rod. In the ensuing summer splendid crops of peas, beans, potatoes, etc., were produced, and the following year brassicas were entirely free from club root.

It is a good plan to make periodical applications of lime on light, sandy soils, such as we have to deal with in this neighbourhood—say every three years—and omitting the usual dressing of manure. Lime may also be applied to heavy land with advantage, as it possesses the dual property of making heavy land porous and lighter, and light land heavier and more retentive.—C. NIPPARD, *Bournemouth.*



A SATISFACTORY AND USEFUL METHOD OF VEGETABLES GROWING ON A ROOF.

Digitized by Google

THE FRUIT AND KITCHEN GARDEN

Chinese Artichokes.

STACHYS TUBERIFERA is the correct name of this artichoke. The tubers are small whorled or corkscrew formed, very prolific and quite hardy. The tubers are at their best now and may be lifted from the border as required for use. If it is necessary to lift the crop the tubers should be laid on a cool base in any shed, but covered with sand to exclude light and air. Light discolours them and air causes them to shrivel, then the tubers are useless for cooking. Care should be taken to pick out every tuber or broken tuber as, if left in the soil they will grow again the following year and become very troublesome. As this vegetable will thrive in all ordinary garden soils, those cultivators who have difficult soils to deal with should plant a few rows of tubers in the spring. They will answer well if planted 9ins. apart in rows 18ins. asunder and covered 2ins. deep, then the crop may be left there and used as required from for three years before they are lifted for replanting in another part of the garden. The tubers should be boiled just the same as potatoes and served with roast beef or poultry. If, after boiling, they are nicely browned in fat before a clear fire, they are quite crisp and a delicious food.—G. G.

Forcing Seakale.

THE forcing of seakale may be undertaken at any time now, and is quite simple even to the veriest novice. However, I have preferred to illustrate my remarks by the addition of a few simple diagrams which I hope will be helpful. The forcing may be done in pots, boxes or in any other kind of enclosure, and a good position for it in any case is beneath the staging of a greenhouse. This method I have shown in Fig. 1. It will be seen that the seakale is planted in a box. This is set beneath the staging and a layer of leaves is put in the bottom. Then a layer of soil is added and the seakale roots are arranged at a few inches apart in the soil, the crowns being about 2ins. out of the soil. After a good watering and a reasonable time being allowed for the draining away of the surplus moisture, the top of the box is placed so as to exclude the light entirely. There must be sufficient room in the box for the tops of the seakale to grow freely. In this sketch also I have shown how asparagus may be forced over the seakale by growing this in a box-like enclosure on the staging.

Another good method of growing seakale for forcing is to use those large pots which are now becoming free from the chrysanthemums. That is shown in Fig. 2. The principle is precisely the same as in the case of growing it in boxes. A large crock is placed over the drainage hole in the bottom of the pot, and is followed by a layer of leaves. Some soil is added, and then the roots are arranged in precisely the same way as in the boxes. A good watering is given as before, and the other pot is inverted over the first when the tops have dried somewhat. A piece of moss is stuffed into the hole in the covering pot, or a piece of slate is placed over it. Adjoining this sketch is shown the root as it is dug from the plot. The smaller roots are cut away as shown by the black lines and these are used for making cuttings for forming a new plantation; as also shown, they are cut with a straight cut at the top and an oblique one at the bottom. The reason for this is that one may more easily know the difference between the top and bottom when they are bundled up like asparagus and plunged in soil, ashes or sand outside till they can be planted in the spring.

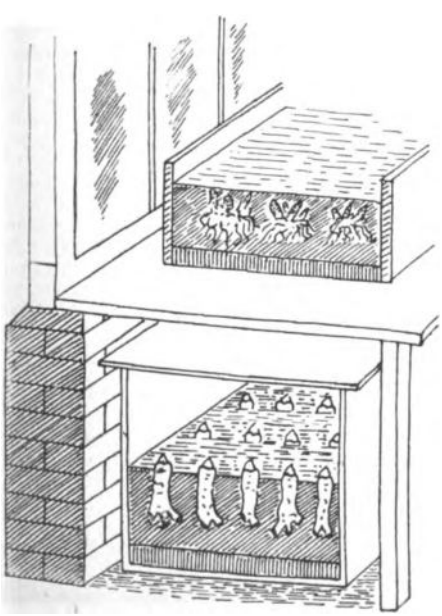


FIG. 1.

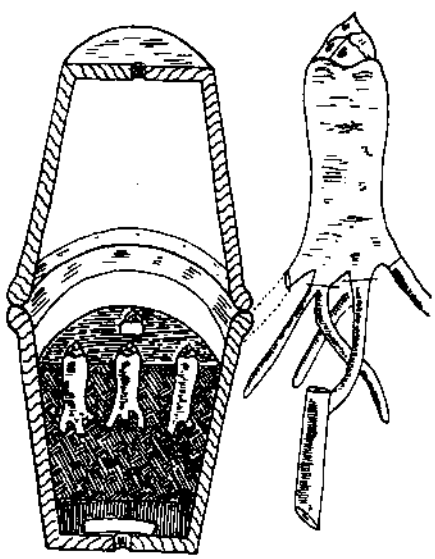

FIG. 2.

I have also included a sketch, Fig. 3, showing the way seakale is forced on the plantation without lifting it. It may be covered with special seakale pots, but anyone who has not these pots would be foolish to buy them, as the forcing can be quite as well done with the aid of boxes. The plantation is cleaned and the bottomless boxes are placed over several clumps. The top is then put on, as it will have to be kept on to keep the seakale dark, though movable when it is desired to examine the seakale or to cut it. In order to get the seakale in use more quickly, some stable manure or fallen leaves are piled up over and around these boxes, as shown in the illustration. The box is, of course, covered on all four sides, the one side being shown open in the sketch in order the better to show how the work is carried out.

In order to ensure a succession of seakale, some roots should be brought into the greenhouse every week or fortnight, and in the open several clumps should be covered at a time. If more convenient all the roots which are likely to be needed for forcing may be potted or boxed up at one time, keeping them in a cold frame or a cold shed till it becomes necessary to bring them into heat. The final sketch shows the manner of cutting the seakale. When cut in this way some more growths will be thrown up which will prove useful, though much thinner than those at first produced.—W. F. R.

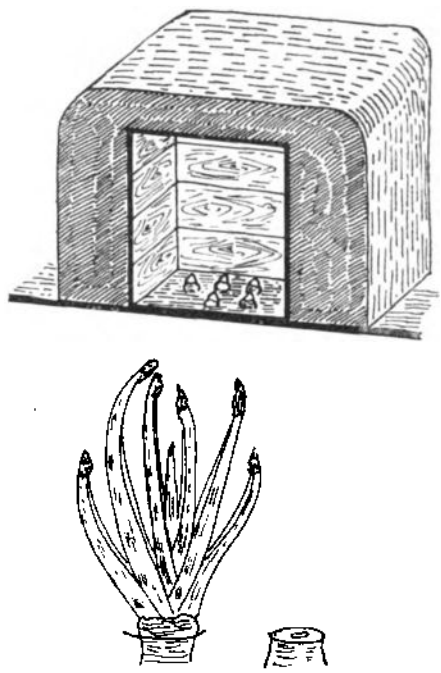

FIG. 3.

Self-Fertility and Self-Sterility of Apples.

IT sometimes happens that we find in our gardens an apple tree which every year produces a tremendous show of blossom yet fails to set fruit or at any rate only a few fruits. It is likely that this yearly show of blossom, with no fruit, is due to the absence of another variety of apple, flowering at the same time, to act as a pollinising agent.

The apple flower is termed hermaphrodite, *i.e.*, it has both the female organs (stigmas) and male organs (stamens—upon which the pollen is borne), present in the same flower, yet in spite of this no fruit is formed. A variety which cannot use its own pollen for the purposes of fertilisation is said to be self-sterile.

Apple varieties may be divided into three classes :—

I.—*Self-sterile*.—Where no fruit is set by fertilising with its own pollen, *e.g.*, Cox's Orange Pippin, Royal Jubilee and King's Acre Pippin.

II.—*Partially Self-fertile*.—Where few fruits are set by self-pollination, but not sufficient to produce a crop. This class includes Worcester Pearmain, Beauty of Bath, James Grieve, Lane's Prince Albert, Newtown Wonder, etc.

III.—*Self-fertile*.—Varieties which will give a good crop when self-pollinated, *viz.*, Rev. W. Wilks, Ribston Pippin, Rival, Duchess of Oldenburg, etc.

It will be seen from a study of the above varieties, that to obtain a good set of fruit it is necessary, in a large number of cases, for more than one variety to be planted or to be found in the neighbouring vicinity, so that bees and other insects which act as pollen carriers may cross pollinate the trees. Cross pollination is the transference of the pollen of one variety to the stigma (female organ) or another in order that fertilisation may take place.

FACTORS AFFECTING THE SELECTION OF VARIETIES.

It has been found that different varieties of apples blossom at different times, and there is a difference of six weeks between the first variety to blossom and the last variety to blossom. On an average the period of blossoming of a single variety is eighteen days, so that it is possible for the blossoms of one variety to have fallen before another comes out. The effective period of blossoming *i.e.*, the period during which the pollen of a variety may be used for cross-pollinating, may be taken as nine days, two days before full blossom and seven days after. Thus, when we are selecting varieties to plant together in order that cross-pollination may take place, it is necessary to choose those varieties whose effective blossoming periods overlap by at least four days. We rarely find two varieties whose effective blossoming periods coincide.

There are three methods which may be employed to secure cross-pollination.

I—*Interplanting of Varieties.*—In an orchard or plantation it is seldom advisable to plant too large a block of any single variety, even a self-fertile variety. Cross-pollination always gives better results than self-pollination. Every fourth row should consist of a variety which will act as a cross-polleniser in order to secure the best results. However, it is not always desirable to take out an entire row, so it may happen that it is better to top-graft a number of the less profitable trees in the orchard with the variety for pollenising.

II.—*Grafting in a Variety.*—In a garden there may not be room to plant another tree, so in this case one of the branches of the tree may be cut back and scions of a variety which blossoms about the same time grafted in. It is best to get a variety whose vigour is about the same as that of the tree into which it is grafted. This will ensure, when grown, a sufficient quantity of pollen available for the bees, etc., to work upon.

III.—*The Tin Can Method.*—This method consists of taking a number of tins, two or three per tree, filling them with water, and placing in them branches of a variety bearing flowers when the tree is in full bloom and hanging them in the tree. This method is not so desirable as I or II, as it entails getting the variety for cross pollinating and keeping the tins filled with water while blossoming lasts.

Any variety which is in blossom at the same time as another will successfully cross-pollinate it. Up to the present no record of inter-sterility among apples has been found.

The following are varieties suitable for use together to secure cross pollination owing to the overlapping of their effective blossoming periods :

1.—Cox's Orange Pippin with Beauty of Bath or Stirling Castle or Bramleys.

2.—Bramley with Newtown or Lane's Prince Albert.

3.—Allington with Worcester Pearmain or James Grieve.

4.—Warner's King with Stirling Castle.

Any variety in Group 1 will act as an effective polleniser for any other variety in that group, etc. H. D. BENNETT.

TRAPPING MICE

GARDENS and glasshouses are frequently much overrun by mice, and not everyone knows how effectually to trap these little pests. The wood mouse (Mus sylvaticus) is the largest of the species, and is seldom seen in the daytime, unless disturbed from its home underground or from any old bags lying about or stored away. But at nights this little animal is very much alive, and first comes to peas and beans sown in the garden. When the grapes are ripe in the glasshouse in some way the mice get in and nibble at many bunches of fruit. Similarly, they are very much to the front in the fruit room; in fact, they seem to have an uncanny way of finding their way in everywhere. Their plan of action is to go to the ripest apples, cut them in pieces in every direction, make a most filthy mess, and then, mostly, to eat only the ripe pips of the apples. The remainder is left in a sodden heap of apple pulp. The old-fashioned straw beehive, or skep, is a famous spot for the wood mouse to make its home. Especially is this so in cottage gardens, when an old bag or two is thrown over the hive for the winter and perhaps a broken pan over them to keep out the wet. This is a much favoured residence for this mouse; at times it gets into the hives and clears up the honey.

In sowing peas and beans some gardeners pour a little oil on the seed and shake them up so that they may be wet all over; then sprinkle some red lead powder over the lot until they are covered completely. This is generally enough to check the mice, but trapping must sometimes be resorted to. A sunk jar (Fig. 1) is a very simple and effective trap. Sink the jar nearly level with the surface of the ground, half fill with water, well grease the inner ledge with lard or dripping, letting it hang on in lumps, and place corn, grease, etc., close to the jar. The mice, attracted by these morsels, will, while "licking the platter clean," slip over the greasy edge into the watery depths below. Another effective trap is shown in Fig. 2. A piece of slate or board is placed flat upon the ground; two sticks, each with a slit in the top, are forced into the ground on either

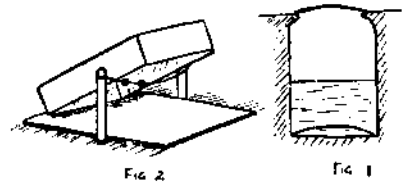

FIG. 2 FIG. 1

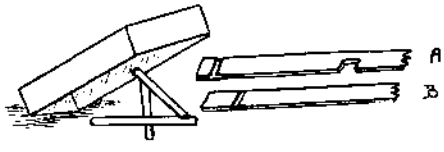

side; next two sprouting peas or beans are strung upon a piece of well greased thread, the peas being about an inch apart, and the thread, with a knot at each end, passed down the slits so as to hang loosely. A brick is then placed on the slate at one end and allowed to rest on the thread, which its weight will render taut. Its height then should be 2ins. to 3ins. The mice, attracted by the grease and peas, gnaw through the thread in their endeavour to eat the bait, with the result that they are crushed to death by the brick. Another trap is shown in Fig. 3. It is known as the figure of four trap, and is composed of three sticks and a brick or tile. The sticks should be flat, about an inch broad and one-eighth thick; the horizontal one should be about 8ins. long, the other two about half that length. The upright one is plain; the horizontal stick is pointed at one end to hold the bait (cheese, lard or fat), has a deep notch cut in its side about half its length, and another cut in the flat surface near the other end (Fig. A). The remaining stick has a notch cut in the flat side about ¾in. from one end, and the other end thinned down slightly (Fig. B). To set the trap, place the plain stick upright next the short one, with the notch resting on the top of the upright, and then the horizontal stick in such a manner that the notch in its side fits the upright and the slanting stick rests in the notch on its face. The brick is then placed so that its weight falls on the free end of the slanting stick. The mouse in nibbling the bait upsets the balance of the trap and brings down the brick upon itself. Mouse clams or gins may also be baited with a cobnut tied on the bridge of the clam with fine wire; if tied on with thread or twine the mouse bites this asunder.

A strange fact about the wood mouse is that the rougher the night (wind or rain), the more likely it is to be caught than on a still, fine night.—R. E. DAVIES, *Oswestry.*

Worms in Pots.

EARTHWORMS should never be tolerated in pots, for these will damage the roots as they force their way through the soil and also tend to stop up the drainage hole at the bottom. The presence of earthworms in pots is usually indicated by the casts which appear on the surface of the soil. Often the worms can be secured by giving the pot a sharp tap at the side with a piece of wood. This makes the worms come to the surface of the soil, when they should be at once seized before they have time to escape. Earthworms are very quick when alarmed, and there should be no hesitation in grabbing those that do appear. When this plan does not succeed the ball of earth should be carefully removed from the pot. If this is done quickly it is quite likely that the worms can be detected at the bottom or sides of the soil, from which positions they can be pulled away. Here again the worms may prove too quick for one, and on the ball being removed from the pot they will retire to the centre of the mass. A very sure way of clearing out all the worms when other plans have failed is on the following lines: Heat some water to a temperature of about 120° Fahr. Care should be taken to see that the water is not hotter, or damage to the roots might result. At this temperature there is not the least fear of doing any harm. When the soil is rather dry, water the plant with the warm water, and this will send the worms either to the top of the soil or else to the sides of the ball of earth. The worms are not in any hurry to go back into the warm soil and can be easily secured.

Worms in pots are such a nuisance, and will often do so much harm before their presence is suspected, that it is important to take steps to keep them out of the pots. Small worms may be easily overlooked in potting soil, and a sharp look-out should be kept so that these can be thrown aside. Some gardeners mix a little soot with the soil used, which will make the tiny worms anxious to get away as soon as possible. From the point of view of the plant, soot is useful, for it is a valuable fertiliser. Never stand pots on loose soil or on any other free matter through which the worms can work their way up into the pots. A firm bottom of coal ashes is the best standing ground for pots, as it is impossible for a worm to force its way through this material. Pots in which strawberry runners are being rooted are particularly liable to be attacked by worms. Here it is an excellent plan to place a few ashes under each pot. This will generally keep the worms from penetrating even when the pots are half sunk in the soil. Of course, when the pots are completely sunk the worms may crawl over the edge. In such cases surround-ing the pots with rings of ashes will keep the worms at a distance. Ashes, whether in a wet or dry state, are very much disliked by worms and form one of the most effective barriers known.—L. B.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Owing to the number of hints which are sent in, we desire that, in future, each hint should be sent in on a post card, and should be limited to 150 words. Payment for these hints is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT.

Christmas Decoration: A Poppy-Head Idea.

Evergreen foliage, or autumn-tinted leaves and berries are extremely decorative in the house when fresh flowers are scarce. If the sprays of leaves and berries are painted over with ordinary shellac, the leaves last indefinitely and do not dry up, neither do the berries swell and burst with the heat of the room as is generally the case. One of the prettiest effects I have ever seen, were some above treated leaves falling in graceful sprays from an old earthenware jug. Giving a bright touch of colour and enhancing the green, were some large poppy heads, which are treated as follows. (The heads are bought for 1½d. each at any chemists.) Place in boiling water and if whole, when dry, paint over with poster paint, or gild. If open—as some usually are—cut where soft between the ribs of the head. Cut off the crown and place it with a pin inside. Put fingernail under the ribs and pull gently, snapping away soft flesh of poppy. The extremely pretty result is stamens. Allow to dry and paint over with poster paint, or gilt, or the two may be used in artistic combination. Push a stick of privet or any likely wood in stem. This mode of winter decoration is uncommon and beautiful, while the heads last for years without losing their freshness.—C. E.

Roses on Their Own Roots.

Having been successful for several years in raising roses for my garden from cuttings at this time of year, it occurred to me that the method would be welcomed by the readers of THE GARDEN. Take cuttings of rose shoots which have flowered this year and are well ripened, and cut them in lengths of 6ins. or 8ins. Cut off a short piece from the top and cut level to a bud at the other end. Now dig a narrow trench, the back of which should be firm, and put the cuttings against this side about 2ins. or 3ins. deep and 3ins. apart. Put some sand around the cuttings, fill in the soil and press very firmly with the foot. If all goes well these cuttings will make nice little plants in a year's time and can be transplanted. I may add any kind of rose will root.—G. J. W.

Dried Fowl Manure for Potting.

Potting composts can be considerably enriched by the addition of a small percentage of guano or some other all-round manure. A good "home-made" guano may easily be collected from the fowl-houses, and this will furnish a sufficient supply for the needs of the potting bench. Fowl droppings are a very rich manurial substance, but pigeon manure is even better.

Collect the substance before it is allowed to cake or get trampled together; when dry, store it in bags in any dry position. When thoroughly dry it will not smell in the slightest degree; but should the drying process not be complete, a little gypsum, a very cheap lime compound, will keep down the odour and at the same time enrich the manure. When the guano is dry it can easily be passed through a riddle and rendered suitable for potting purposes. Never use this manure if it contains sawdust. As a result of using this manure splendid plants have been obtained by the writer.—W. A. W.

A Use for Old Venetian Blinds.

Venetian blinds are now out of date for windows, but they may still often be found reposing on the floor of attics or may be picked up cheaply at auction sales. The laths of these can be put to many uses in the garden. Cut in two they make excellent boxes for the sprouting of seed potatoes, the thicker laths at top and bottom being used where strength is required. They are also capable of being used for light trellis-work for roses or climbers in unexposed positions. The laths, though thin, are wonderfully strong, and if kept well painted they last a surprising number of years. The writer has used them, too, for the formation of hurdles for the protection of tender shrubs in winter. Packed with straw, bracken or gorse, they keep off frost excellently. Frames of these laths with scrim tacked on may be placed against espalier fruit trees in spring during the critical nights when blossoms are setting. The present month is a seasonable one for the formation of these structures. Other uses may occur to the reader.—L. D. W.

A Useful Tool for Lifting Turves.

Those who wish to cut some turves from the lawn for relaying and do not possess a specially made tool for the purpose, will find the following a very efficient tool. Get a Dutch hoe (solid type), which must be sharp and in good condition, put in a fairly stout handle from 4ft. to 5ft. in length, according to the comfort of the user, a steady pushing action must be used and it will be found that the thinness of the blade, and also the crank, will make it a comparatively easy job to cut turves perfectly even, which is so necessary when they are wanted for relaying purposes.—W. E.

Repairing Grass Edges.

From various causes the edges of lawns and borders are apt to lose their even outline, and as the defect is most noticeable there is a general desire to repair it effectively. If small pieces of turf are used they will not remain long in position, and if the difficulty is overcome by using pegs, the job is rarely satisfactory. The best and only reliable method is to remove a square of turf, including the damaged part, and turn it round so that the straight edge is outside. The broken portion can then be repaired with a little fresh turf, if necessary, and the object in view accomplished with complete satisfaction.—C. J. C.

Hints on Planting Fruit Trees.

On clay soils, the roots of trees often suffer from lack of air and have no power to resist dry seasons. A good way is to take out a hole, 2ft. 6ins. to 3ft. deep and nearly twice in width, then place a layer of hedge clippings or similar material 6ins. deep, with a layer of soil of similar depth, then another layer of clippings and soil, then plant the tree in the usual way. Fruit trees thus planted I find make wonderful headway and resist diseases so well that readers should try this way with a tree on heavy clay soils and watch results.—H. M. B.

OUR SERVICE BUREAU

Though so many subjects are dealt with in each issue of THE GARDEN, *it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, there is always information available from a staff of expert contributors and consultants; and there is no charge for this. It is one of the additional means of service which* THE GARDEN *is glad to render to its readers.*

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope and the coupon, that will always be found in each issue, shall be sent with the enquiry. We would point out, however, that we cannot undertake to supply readers with plans and designs of gardens, but will willingly assist in giving suggestions for planting.

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2.*

We have selected the following enquiries, with their answers, as being of more general interest, and therefore worthy of publication.

Dwarf Shrubs for a Shady Border.

I have a bed, about 14ft. by 6ft., planted with bush roses, but since a pergola covered with rambler roses has been put up on the south-west side of bed, the roses do not flourish, the bed being partly shaded. Also, a wall on the north and east sides of bed is near, which makes it, I think, too airless for roses. I think of moving the roses to a more open position, and ask your advice as to what I could plant in this bed; it runs north-west and south-east, and is sheltered from all cold winds, rather heavy, clayish soil, a damp climate, subject to droughts in spring and early and late frosts. I should like some dwarf flowering shrubs for centre of bed, something fragrant and showy?—G. D. J., Llandovery.

We suggest that you plant four plants of Philadelphus Lemoinei erectus at the back and three plants of P. microphyllus in front would be most suitable for your purpose. P. microphyllus is very fragrant, and, if preferred, you could have seven plants o this variety instead of four of P. Lemoinei erectus.

Aquatics for a Small Tank.

I have two small tanks sunk in the ground in a rock garden and wish to plant a water lily in one. There is, I believe, a certain variety of nymphæa particularly suitable for this purpose and shall be glad if you can tell me the name of it and the best method of planting. Also, is there any other aquatic plant suitable for the other tank? The tanks are about 2ft. 6ins. in diameter and about 2ft. deep.—B. H. B., Cambridge.

Varieties of nymphæas suitable for growing in the small tank which you mention are the

Digitized by Google

following: N. candida, N. Laydeckeri fulgens, N. Pygmæa alba. All these are suitable for tub culture and are obtainable from Messrs. Perry, Hardy Plant Farms, Enfield, Middlesex, from whom information regarding their culture will only too willingly be given.

Other aquatic plants suitable for growing in tanks are: Aponogeton distachyon; Menyanthes trifoliata; Calla palustris. These must only be grown in shallow water, and must have some soil in which to root, as they really might be considered, properly speaking, as marsh plants, rather than pure aquatics. The only aquatics which are suitable for culture in tanks are a few, such as the following: Callitriche verna; Elodea densa; Ranunculus aquatilis.

Climbers for a Fence.

I have bought a new house near Harrow, with a garden 270ft. by 30ft., heavy clay soil, open stake fencing, one facing north-east, the other south-west. Would you be so good as to advise me what evergreen climbing plants will succeed on these fences, to form a screen? I propose to plant also a Climbing Ophelia rose and Gloire de Dijon.—F. H., Highgate.

We would suggest the following for the various positions you mention:

North-east Fence.—Jasminum officinale, J. nudiflorum, Pyracantha Lalandei, Ceanothus thyrsiflorus, Escallonia langleyensis, Rose Albéric Barbier.

South-west Fence.—Ceanothus dentatus, Escallonia rubra, Pyracantha angustifolia, Cotoneaster Henryana, Trachalospermum japonica.

Low-Growing Shrubs for Walls.

I desire to plant shrubs near the walls of my house for the purpose of hiding from view the lower portion of rain-water pipes and the gullies into which they discharge. One wall faces south and the other west, while the subsoil is clay. I should be glad if you would advise me as to suitable shrubs. They should be evergreen (flowering preferred), not exceeding about 3ft. in height when fully grown, and bushy.—H. R., Middlesex.

It is difficult to suggest wall shrubs which do not grow more than 3ft. in height. Almost all wall shrubs attain a height greater than this, but, of course, many of them can be kept in check by regular pruning and cutting back. We should suggest for your south wall one or two species of ceanothus, such as thyrsiflorus, rigidus or dentatus; tamarix, which should be given a fairly sandy soil if possible; Cotoneaster horizontalis; Pyracantha coccinea Lalandei; Escallonia langleyensis, E. Philippiana; Olearia Haasti and Potentilla fruticosa both make bushy shrubs and should be planted near the wall, but they are not what one might term proper wall shrubs. They will both serve very well for the purpose you mention, also Berberis Darwinii. The majority of these, however, need to receive a regular cutting if they are to be kept at a height of 3ft.

Training Cordon Apple Trees.

I have several young apple trees with one straight stem of about 4ft. in length. These have just been planted, and I should like to grow them on as cordons. Will you kindly let me know the procedure?—G. W. G., Berks.

The training of single cordon apple trees is quite a simple procedure. If the trees are about 4ft. high at planting, all the pruning required after planting will be to cut back all side shoots to two buds at the base. There is no need to shorten the "leader" or extension shoot at all. At each subsequent winter pruning, cut back all side shoots to two buds, and if the young extension shoot at the top grows longer than 1½ft., cut it back to this length. Later, you will need to cut the "leader" shoot harder, for it will quickly fill the allotted space. Should you find growth is very vigorous, lift the tree in October, prune back the coarse roots and then replant. The trees should be pruned in summer as well as in winter, the summer work consisting of pinching back all side shoots to about five leaves from the base, these being further shortened at the winter operation, as described. Winter prune each year as soon as the leaves fall, and summer prune in late July. The trees would be best planted at an angle of about 45 degrees, and can be placed 2ft. or more apart in the row or against the wall or fence. They should be trained to a wire trellis, or to bamboo canes tied to wires, stretched taut between firmly planted end posts.

How to Get Rid of Cabbage Butterflies.

For two years my kitchen garden here has been plagued with the common white butterfly, with the result that many of my cauliflowers and broccoli have been destroyed and many others rendered uneatable by the attacks of the caterpillar. Can you suggest any means of preventing this? Possibly by dusting the young plants next summer with something which will prevent the butterflies from laying their eggs upon them a remedy might be effected.—S. M., Gloucestershire.

As it is better not to use a poisonous spray on green vegetables, the usual caterpillar poisons are not available for the treatment of this pest, and it is necessary to depend on less efficient insecticides, which, nevertheless, can be quite effective if thoroughly applied. The following solutions can be tried with some success:

Soap, 1½–2 oz.; water, 1 gallon; but if the water is hard, use 2 oz. of soap.

Common salt, 2 oz.; water, 1 gallon. This solution has been in use for a long time, and appears to give good results.

If these do not prove sufficiently effective, naphthalene emulsion is worth a trial. Slaked lime in powder form, or a mixture of lime and soot, are useful for dusting on the plants when damp. These remedial measures should be undertaken as soon as the earliest signs of attack appear, and subsequent washings given according to the spread of the disease.

A Screen for the Kitchen Garden.

I would be much obliged if you would advise me as to the following: I want a hedge that will grow to 8ft. or 10ft. high to shelter my kitchen garden, which is very exposed on the north and east sides and close to the sea, but as it is small, only about 12 or 14 rods, I want something that has not spreading surface roots and does not impoverish the surrounding ground. I thought of either beech or hornbeam as suitable, but should be glad if you will inform me as to which is the better of the two, or if there is anything superior kindly let me know, but please take cost into consideration, as I do not want anything too expensive. The soil is a medium red loam, situation 307ft. above sea and about 300 to 400yds. from cliff edge.—C. A. B., Teignmouth.

We should certainly advise you to plant Cupressus marcocarpa as a hedge to shelter your kitchen garden. Although beech and hornbeam are both suitable, cupressus is an evergreen plant, and will provide most shelter in the winter months, especially in an exposed situation. It is a fairly rapid grower and will soon reach a height of 8ft. to 10ft., and it is not a particularly gross feeder. Plants can be obtained 2ft. to 3ft. high and planted at a distance of about 2ft. apart. Plants of this size can generally be obtained at a cost of about 1s. 3d. to 1s. 6d. each, but there is often a reduction in price when a large quantity is ordered. As well as making a most effective hedge, it is very decorative all the year round.

Pruning Climbing Roses.

Can you advise how much to prune Climbing Lady Hillingdon on a house wall? In five years it has made splendid growth, reaching the roof and making strong growths, too many to tie in. It flowers well, but is never a mass of bloom like Gloire de Dijon. Aspect south-east, sheltered by bay windows. It is top-dressed with farmyard manure every spring.—B. M. B., Towcester.

Before doing any pruning to your roses, it would be well to consider the possibilities of laying-in young shoots from the base, so as to have a succession of young wood to take the place of the older which, a few years hence, will cease to yield satisfactory blooms. Generally, vigorous climbing roses throw up some strong shoots. The strongest should be retained full length to furnish the upper part of the wall. Two or three of the next best should be shortened sufficiently to make shoots to cover the lower portion of the wall. Any weakly shoots should be entirely removed. The surplus growths, which cannot be tied in, should be pruned fairly hard back to the main stems, much in the same manner as is done with standard roses. This pruning and the shortening all the young shoots should be done early next March.

Shrubs for Under Beech Trees.

I shall be much indebted to you for your advice as to what is the best shrub or bush for growing under trees. I have two large trees (chestnut and beech) in front of the house between it and the road, and nothing will apparently grow between them and beneath their branches, which touch each other. The space I wish to block out runs to a height of about 15ft., and I should like something bushy and, above all, quick growing. Perhaps you could suggest one or two suitable shrubs for the purpose.—C. M., Birkenhead.

We should suggest that the following are suitable shrubs for growing under trees: Mahonia Aquifolium, a low-growing and spreading plant, evergreen and reaches a height of about 1ft. The Rose of Sharon (Hypericum calycinum), another low-growing plant of rather a spreading habit, and most effective when studded with its sulphury yellow rose-like flowers. It does particularly well in a shady position under trees. Sarcococca is another suitable plant, also evergreen, and carries white flowers during the summer months. It is excellent for a shady bank under trees. As well as shrubs, you might also plant a few daffodils or bluebells, which would have a decorative effect in spring.

How to Treat Unhealthy Auriculas.

I should be so much obliged if you can tell me what treatment to give my auriculas. They were planted last autumn, but have not flowered. They grow up a good, strong green in the centre, but when they have about six leaves the outside leaves go spotty and yellow. None of my other plants suffer this way, but it is always difficult to get flowers in London. I enclose some of the outside leaves.—J. P., London, S.W.1.

The appearance of the leaves of your auricula plants denotes an attack by an aphis—root aphis Trama auriculæ. The only effective way of dealing with the pest is to lift all the plants, carefully washing away the soil with soft soap solution, and replant in another border, which has been dressed with Vaporite. The best plan would be to make the new border ready and burn the Vaporite in the soil a week, or so, before you lift and clean the plants. Instructions will be found with the Vaporite, which can be obtained from any good horticultural sundriesman.

CLEAN CROPS *ARE* GOOD CROPS

Those dog-in-the-manger trees

YOU really can't afford them. Fruit trees that don't bear take too much room, and keep light and air from other crops.

Yet this dead loss can be turned into a highly profitable crop by quite unusual cleanliness.

That merely means a thorough cleansing of the tree when it is dormant. This season, trees treated with CARBO last winter have been bent down with fruit, where unsprayed trees have failed completely.

Now is the time to destroy moss, lichens, hibernating insects. Kill the eggs of Aphis, Apple Sucker and Caterpillar. Save next season's fruit crop. CARBO is put up in convenient quantities for the smallest garden as well as the largest. Get CARBO now. It costs so little to spray with this supreme winter wash—and saves so much.

CARBO WINTER WASH

2/6 per quart tin
6/- per gallon can

SERVICE BUREAU.—*Continued.*

Protecting Delphiniums.

I have planted eight very fine delphiniums in my garden and wish to protect them from frost and insects. Will you kindly let me know how to treat them if covered with peat or sand? The soil was prepared some weeks ago.—F. A., Highbury.

The best method of protecting delphiniums in the winter is to apply a dressing of sand over and around the dormant crowns. This prevents the attack of slugs and snails, which are extremely partial to the delphinium. If bracken can be obtained, a few of the fronds might be spread over the plants as a slight protection against frost, but the sand should certainly be procured, as it acts as a deterrent against slugs.

How to Grow Apples and Pears in Pots.

Would you let me know how to proceed with growing apple and pear trees in pots, what compost to use, size of pots, etc.?—H. G. A., Somerset.

A 12in. pot is the usual size needed for apple or pear trees, although very young trees, as bought, might well go into a size smaller. Potting should be done in autumn, and a suitable compost to use consists of 4 parts of turfy loam, 1 part decayed manure and ½ part finely broken mortar rubble, along with a 6in. potful of bone-meal to each barrow-load. This should be turned several times before use. The pots should be well drained by placing crocks, etc., over the drainage hole, and the trees must be firmly potted, a wooden rammer being used. Pot-grown apples and pears can stand out of doors from June until February, inclusive, being taken into the house only to bring them on earlier and to safeguard the blossom. They are by no means difficult to manage successfully, though close attention must be given to the top-dressing, watering, syringing, summer and winter pruning, and re-potting, as this becomes necessary every other year.

Pruning a Young Apple.

Will you please advise me on correct pruning in the following case? A bush apple, Ellison's Orange, was planted December, 1915, the tree at that time being five years old and worked on the Doucin Paradise. In February, 1926, I cut the leading shoots back by about half; they were about 3ft. long and I reduced them to 18ins. or so. This year the buds I cut back in February have only made about 1in. or 2ins. of extension growth. Shall I leave the tree unpruned this winter?—A. M., Bridport, Dorset.

We think it most unwise to leave the Ellison's Orange bush tree unpruned this year. It is surprising that it has made so little new growth. We think your best plan will be to cut back beyond the short extension growths made to a plump, healthy-looking bud just below this; that is, to about an inch or so below where you cut last January. It is no use leaving the short extension growths intact or cutting to the base of them, for this is useless growth to leave. If you cut below this, however, to the topmost healthy bud, then strong growth will undoubtedly follow. We would further recommend you to lay a mulch of stable or farmyard manure over the tree roots next February as an additional inducement to make good growth next summer.

NEW CHRYSANTHEMUMS.

NO fewer than seventeen new chrysanthemums were submitted to the Floral Committee of the National Chrysanthemum Society on November 30th last, when they gave awards to seven of them.

Aloma.—This is probably the largest incurved chrysanthemum in cultivation, and while the florets are not quite so regularly disposed as those of the most desired exhibition varieties, the rounded, bright straw-yellow blooms have great decorative value. First-class certificate. Shown by Messrs. Keith Luxford and Co.

Crimson Dawn.—A handsome single of bright ruby crimson colour with a narrow golden zone and a small disc. First-class certificate. Shown by Mr. H. J. Jones.

Delightful.—An exceedingly useful single white variety of compact, rounded form and substantial florets, which last well when the flowers are cut. Shown by Mr. H. J. Jones.

Dora.—A large single of uncommon fawn-peach colour which will appeal to private gardeners more than the market grower. Shown by Mr. H. Shoesmith, junr.

Guardsman.—A handsome large single with three rows of bright crimson florets. First-class certificate. Shown by Mr. H. Shoesmith, junr.

Mrs. W. Turnham.—A large single of great substance, but carrying too many rows of florets to be first class. The tips recurve gracefully, the disc is small and the colour is a rich crimson. Commended. Shown by Viscount Hambledon, Greenways, Henley-on-Thames.

Ruddigore.—A splendid Japanese variety of the best market size and form. The rolled, graceful florets are of a glowing chestnut colour. First-class certificate. Shown by Messrs. Cragg, Harrison and Cragg.

Valerie.—This is one of the most useful singles that has been raised lately. The flowers are of Mensa type, the florets have plenty of substance and are of reddish terra-cotta colouring, flushed with rose dore. First-class certificate. Shown by Messrs. Keith Luxford and Co.

BOOK REVIEWS.

IF there is one book which has influenced English gardening and gardens to an extent, it is surely "The English Flower Garden," by William Robinson, first published in 1883 by John Murray. Its popularity and usefulness are by no means on the wane, as can be judged by the fact that it has gone through thirteen editions and that another has just been published at a price of 24s. net.

In the present edition the text has been thoroughly revised and the subject matter brought up-to-date, in keeping with the many new introductions of good all-round garden plants from various parts of the world, notably from the East, during the last twenty years. Much valuable information is given on the behaviour of many of these new plants, including herbaceous and shrubby subjects, in the gardens at home and the positions best suited to their culture, so that the experimenter with these new arrivals will find something of interest and instruction in the pages. Some of the newer sections such as that devoted to primulas and meconopses, are not completely up-to-date, but on the whole they cover those representatives of the genera which are finding their way into general cultivation in this country. The information given on the individual species is as accurate as it is possible to be, since the majority of the plants have only been under observation for a comparatively short time and their behaviour under varying climatic conditions and the soils of varying compositions is as yet not known. For example, P. Forrestii is stated as "not hardy in the open in England." Up till recently this was thought to be true, but now further experiments with the species show it to be hardy in our western and southern districts, and even in the north if it is given a position in the rock garden or wall which it likes. It is not so much a question of hardiness with this plant as one of situation. But this is a minor point considering the amount of material in the book and may well be overlooked since it is of

Digitized by Google

intended as a book for the specialist, but rather as a valuable guide to the general gardener, who is a lover and grower of flowers. As such, it is an excellent book, which will remain for some time as the standard work on the subject.

We are to some extent in sympathy with the opinions expressed in the Preface to this edition regarding the use of English names for flowers and the more modern practice of employing the Latin form. The whole question is an involved and difficult one and cannot be dismissed lightly. There is much to be said on both sides, but from the amateur gardener's standpoint more publicity ought to be given in trade catalogues, books and other publications to revive the usage of English names. If such a course be followed it will be found to have a more stimulating influence on gardening in this country and bring it away from the hands of a comparative few to within the reach of the many.

It is unfortunate that additions have not been made to the list of illustrations, as the book would have gained considerably in value. Nowadays, with the rapid advance and progress in floral photography, woodcuts are out of fashion and although they are admirable in every way, yet a half-tone illustration teaches more. Still, with their inclusion the volume would have lost much of its old-world atmosphere, which has characterised it throughout all its editions.

For those gardeners who do not know it, it is a book worth obtaining, and for those who have a copy of an old edition, the present one is worth putting in its place, since it is entirely up-to-date and alive to all the problems of present-day gardening.

Readers of THE GARDEN may recall a series of articles under the title of "John Richard Anderson: His Garden Diary," by Dion Clayton Calthrop, which appeared in our issues a number of months ago. To those who enjoyed reading them we would draw attention to a small volume, "A Diary of an Eighteenth-century Gardener" by Dion Clayton Calthrop (Williams and Norgate, 7s. 6d. net), which has just been published. The book contains a number of the articles which appeared in THE GARDEN, with considerable additions, and the whole presents a most charming picture of gardening life and pleasure in the eighteenth century. The volume is decorated with well executed line drawings by Eleanor Brockdale.

There are few modern books on the subject of Herbs which deal explicitly with the number of our herbs and their uses and a recent publication, "Herbs of Healing," by Edward Step (Hutchinson and Co., 10s. 6d. net), will therefore be welcomed by all those interested on that account. In its pages the author, well known as the writer of several reliable handbooks on various aspects of native plant life, has endeavoured to describe a number of our native plants which are reputed to have medicinal properties. The majority of these are simple herbs of the field, but a few woody plants of medicinal importance are included. In each case the qualities and uses of the herb are described simply and accurately and then follows a clear and concise description of the plant and its habitat. Unfortunately, there is no mention made of garden cultivation, which is to be regretted, as many would have welcomed suggestions on how to grow these simple plants in their own garden. The keen gardener, however, should find the information available on soil and position of the plant when growing wild of great help when he turns to garden culture. Instruction, interest and not a little amusement are combined in its pages. It would seem that many of these herbs have a kind of supernatural magic about them and may be taken internally or externally as a perfectly safe cure for all ailments. Certainly the therapeutic value of many is well established; but others have fallen into disrepute, largely by the importation of exotic plants in which the active principle is present in large and more easily obtainable quantities. The book is well illustrated by some seventy-six illustrations from photographs by the author. The majority of these are clearly reproduced and certainly show the nature of the plants in the living state, which will be an aid to any who collect herbs either for drying purposes or home cultivation.

"The Story of the Plants," by Grant Allen. (Hodder and Stoughton, 2s. 6d. net.) This is a new and fully revised edition of this popular little work, which is now to be included in the Peoples' Library. That it has proved popular is evidenced by the appearance of this second edition. It is written in a simple and charming manner, yet accurate in all its information.

Trees probably by reason of their majesty, age and character, have come to be surrounded with a certain air of mystery and fascination and it is always interesting to read of their ancient lineage and to learn something of this web of romance which has been woven around them. In this connection, a volume, which has just reached us, "The New Book of Trees," by Marcus Woodward (A. M. Philpot, Limited, 12s. 6d. net), is most illuminating and instructive. Much scattered information has been gathered together by the author and presented in the form of a most interesting and unique story, which will make a strong appeal to all tree lovers. The author has tried, and most successful he has been, to give not only the bare scientific descriptive outline relating to our various trees, but also to present a picture of the trees as individuals, with their ever changing expressive moods and character. To do so faithfully necessitates an intimate knowledge of facts, which the author undoubtedly possesses, and the result is a pleasant, readable book, full of information. There is no attempt to introduce scientific technicalities, although simple botanical introductions are to be found at the head of each chapter, giving a short, lucid description of the subject and its uses. Then follows something of the romantic history of the tree and references and extracts from literature. In this way the book makes a wide appeal to the lover of trees, the scientific forester and botanist, the landowner and, above all, to the lover of folklore and nature.

The illustrations, which are all well executed woodcuts and line drawings, illustrate forcibly, but rather harshly in some cases, the essential characters and details of each tree. It is an admirable book and is certain of appreciation by those who love trees, and who among us does not?

TRADE NOTE.

TO those readers who are on the look-out for novelties for table decoration we would draw attention to the new "Beco" rose bowl, manufactured by Messrs. W. Darlington and Sons, Limited, which, as well as being, an attractive bowl for holding flowers, is also the very latest design in loud-speakers. We are not wireless experts, but it appears to be an instrument which is exceedingly efficient and gives a volume of sound sufficient to satisfy the most critical wireless "fan."

CATALOGUES RECEIVED.

Messrs. S. McGredy and Son, Portadown, North Ireland.—A rose catalogue which should interest every rosarian. Several fine new roses which have been raised by this firm are listed.

Messrs. Harrison and Sons, St. James Street, Leicester.—Novelties and specialities in vegetable seeds, including their excellent Brussel sprout, "XXX," which produces particularly heavy crops of large, firm buttons.

THE GARDEN

THE AMATEUR GARDENERS' PAPER

Vol. XC.—No. 2872 Saturday, December 18th, 1926 Price TWOPENCE

FREESIAS ARE AMONG THE MOST CHARMING OF ALL PLANTS FOR INDOOR DECORATION, EITHER FOR THE CONSERVATORY OR FOR THE HOUSE. THE SOFT SHADES OF COLOUR AND THE INIMITABLE GRACE AND POISE OF THEIR FLOWERS MAKE THEM AMONG THE MOST VALUABLE INDOOR PLANTS THAT WE POSSESS. THEIR SUCCESSFUL CULTIVATION IS SO SIMPLE, AND THE RESULTS SO INVALUABLE, THAT NO GARDENER WHO HAS A GREENHOUSE SHOULD BE WITHOUT AT LEAST A POT OR TWO OF THESE CHARMING PLANTS FOR INDOOR DECORATION.

THIS Catalogue, nicely produced and well printed, contains a valuable host of useful hints on FRUIT TREE CULTURE for Amateur and Professional. Herein will be found all the best and most popular Fruits for all purposes, alphabetically arranged for ready reference. A feature has been made of interesting Chats on soils, situations, and fertilizers; in fact, it is a valuable book, which should be in the hands of all those who possess a Garden or Fruit Farm, large or small. Sit down now, while the matter is fresh in your mind, and write for your free copy.

KING'S ACRE ROSES

THE King's Acre Nurseries—famous since 1785 for the stamina and vigour of their roses—have hardy and reliable

Bushes and Ramblers

in a wonderful, almost endless variety, which they are offering at prices considered by experts and amateurs to be beyond competition.

THE GARDEN

VOL. XC.—No. 2872. DECEMBER 18, 1926. PRICE TWOPENCE

NOTES OF THE WEEK.

Crowded Planting of Shrubs.

READERS of THE GARDEN frequently send us planting plans for publication in our pages or for criticism and advice. While those which deal with herbaceous planting are usually excellent and show both imagination and knowledge of plants, those which deal with shrub borders in detail show the reverse. The commonest method appears to be to design the planting plan of a shrub border as if it was devoted to herbaceous plants with the space allowed for each shrub so limited that it is obvious that in a very few years the shrub border would become a tangled thicket with plants growing into each other, a hopeless state of affairs almost impossible to remedy.

This method of planning a shrub border is thoroughly unsound, for it must be remembered that half the beauty of shrubs lies in their form and habit, a beauty that is entirely lost by injudicious and overcrowded planting. One such plan has been sent in recently, that of a little formal garden, excellent and simple in design, but one which would prove a lamentable failure in practice, for one reason and one alone, that the shrub border which surrounds the garden is horribly overcrowded. Here are a few examples: Two standard crabs John Downie one behind the other, and yet the border is only 4ft. 8ins. wide; two standard mays, one Philadelphus Virginal, one Æsculus machrostacha and one lilac in 52 square feet; two standard crabs, one forsythia and one Buddleia magnifica in 40 square feet; and so on. In no single case would a plant have a chance of showing its true form after two or three years' growth; the entire border would soon be a jungle.

The truth is that at the start too sparse planting is infinitely preferable to that which is too close. If the border looks bare during the first year or two annuals may be sown or easily grown herbaceous flowers planted in the bare patches to make a temporary show. The perfect shrub border is rarely seen, and when it is it will be found that the branches of adjoining plants do not interlace. Examine the habits of your shrubs, and the more graceful they are the more room you should allow them. It is always better to overestimate the amount of room they will take up in a few years than to underestimate it.

Question Nights.

A CORRESPONDENT has sent us a report of the Question Night of the Dundee Horticultural Society. This is an admirable innovation that other horticultural societies might well copy. Many societies rely on outside help, such as lecturers, for filling their evening meetings during the winter. In their way garden lectures are useful, in that the lecturer is often a stranger who will deal with gardening outside the particular district in which he is lecturing, thus broadening the outlook of the members and giving them useful hints about plants or horticultural practice which are not in common usage in their particular district; but even more interesting is the fact that an evening meeting was crowded to hear questions and answers on local subjects instituted by the members themselves. This proves that the Dundee Horticultural Society is in a very healthy condition.

The opening question was how the Society could help or encourage the occupiers of the garden city houses to keep their gardens. This was obviously an auspicious start, for the debate was keen and the debaters showed much sound common sense. Other matters debated were such interesting subjects as the correct methods of keeping apples, the deterioration of the constitution of the potato, and that the present-day gardener was as efficient as his predecessor. All were subjects of great local interest, and it will also be seen that many of the subjects were of great national importance, such as that dealing with potatoes. Doubtless the members left with the pleasant feeling that the evening had been profitably spent.

HAVE YOU

¶ *Renewed your annual subscription to* THE GARDEN *?*

¶ *Repaired your old seed-boxes and made as many new ones as you will require ?*

¶ *Overhauled, cleaned and thoroughly oiled your mowing machine ?*

¶ *Completed the pruning and winter spraying of your fruit trees ?*

¶ *Started all constructional alterations in your garden ?*

¶ *Repointed and tied in bundles your pea and bean sticks ?*

¶ *Top-dressed with bone-meal and wood ashes your wall fruit trees ?*

¶ *Transferred from the plunging ground to a warm greenhouse your pots of early bulbs?*

The Frame Ground.

IN many gardens a well sheltered corner is set apart as a frame ground, where frames can be arranged so that mats, litter and other material can be placed on them in the winter to exclude frosts from plants growing in them. Here, all such litter is confined and kept apart from the open garden. In some gardens a single frame only is possessed. In all cases it is important that the necessary protecting material be placed in a dry quarter ready for use when frosts come. At this time all cold frames should be occupied with lettuce, cauliflowers, parsley or endive, or made ready for the gentle forcing of chicory, rhubarb and, later on, asparagus. In cold frames plants are often lost in the winter time from the evil effects of damp. There is not any fire heat in the frame to expel moisture, so the proper thing to do is to take off the glass lights on very fine days and to tilt them when the weather is moderately dry. Even at night and when the glass is covered with mats or straw, a tiny opening for ventilation at the top is advisable, such opening being protected by the overhanging mats or straw. If the young plants, above referred to, are not already placed in the frames, no time should be lost in planting them. They should be planted in a firm bed, not in loose compost, watered once and then only if the soil becomes very dry to guard against excessive moisture.

The Crossword Prizes.

THE two prizes of One Guinea each, offered to the readers who sent in the first correct solutions opened to THE GARDEN Crossword No. 3, which appeared in our issue of December 4th, have been awarded to

Miss M. E. Kenyon,
Park House,
Cheadle Hulme, Cheshire,

and

Mrs. E. Hunking,
3, South View, Conway Road,
Pontypool, Mon.

To each of whom a cheque for that amount has been sent.

We are indebted to Messrs. Carter's, of Raynes Park, for the use of the illustration of Tomatoes, which appeared on the front cover of our last issue. The illustration was that of Tomato Sunrise, a modern variety.

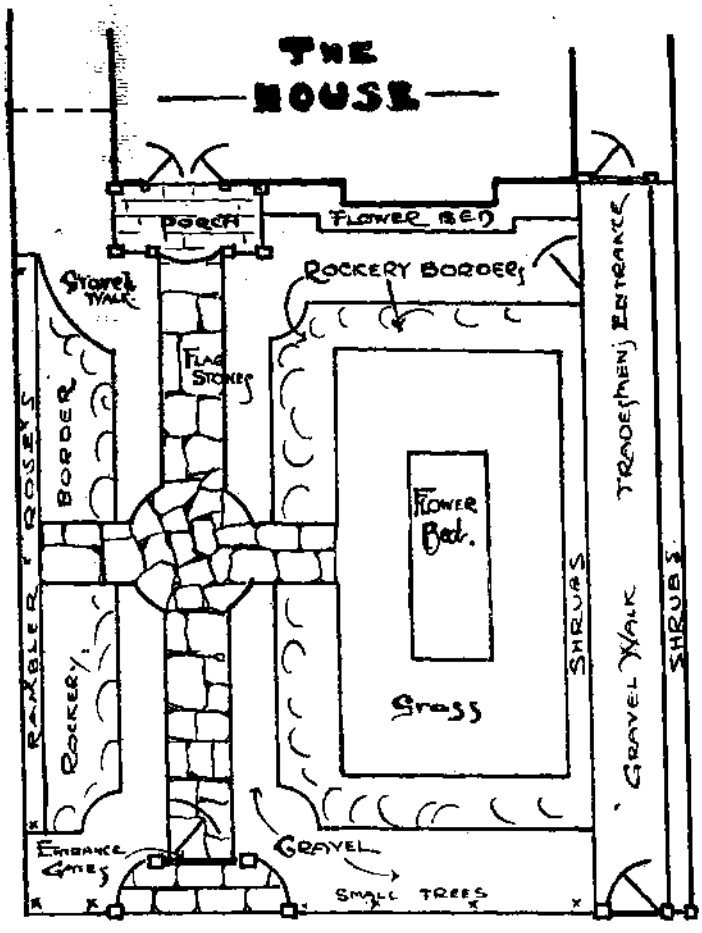
HOW TO MAKE YOUR FRONT GARDEN ATTRACTIVE

This is a point of considerable interest to many readers, and the following suggestions as how best to treat a small area may prove helpful.

ONE thing that adds greatly to the general appearance of a house is an attractive front garden; it does not matter where it is situated, or the size of it; but it is the arrangement that counts so much. How often do we hear a remark passed that some particular house looks nice. Probably the house in question is just one of many others of the same type, but the owner happens to be a garden enthusiast and realises that it is worth his while to make it bright. This can be done in various ways according to one's taste and leisure time available: I know a front garden near here, kept up solely by the lady occupants of the house, whose hedges of shaped golden privet and topiary work of box are really works of art, the neatness and symmetry of which surpass anything I have yet seen. Clipped shrubs certainly look very well if arranged with discretion, but can easily be overdone in small villa gardens. They entail much laborious clipping to keep in shape, to say nothing of the clearng up afterwards.



A SUGGESTED DESIGN FOR A SMALL FRONT PLOT WHICH WILL PROVIDE AN INSTRUCTIVE GUIDE AT SMALL COST.

The rockery border, in my opinion, always looks bright and showy in the front of a house, and it is being adopted more than ever, as such a wide variety of plants can be incorporated therein to make it gay for a long period by the use of perennials, biennials and annuals. Even in the depth of winter it never looks bare, as a large percentage of the foliage is evergreen until the spring appears, when many gems of beauty and colour relieve the situation.

At a dividing or boundary fence something is often needed. Unless absolute seclusion is desired, when a hedge of some sort would be planted, an excellent idea is to fix narrow panels of square mesh trellis (squares about 1oins. by 4ins.), not more than 2ft. wide and 6ft. high, as an ornamental arrangement for training suitable rambler roses. These trellis pillars should be placed at intervals of about 8ft. and connected at the top by light iron chains or ropes, which form festoons between the pillars and should be allowed to hang quite slack, when the roses will gradually be trained along, forming beautiful garlands. If two chains can be used, one hanging about 9ins. lower at the centre, a much better effect is produced. This idea, if erected above a dwarf fence of chestnut, or a low evergreen hedge, not only looks very graceful, but the ramblers can be kept within limited bounds, the sunshine and air being allowed to enter freely.

Another attractive addition for the front of a house or bungalow is wall trellis—not the common oil-shop stuff, but square mesh panels, made specially and properly spaced out and fixed slightly away from the wall. Here again a colour scheme is necessary. For light brickwork, rough-cast or cement walls, nothing blends better than a brown wood-preservative as a coating. If, on the other hand, the walls are of red brick, or brick of a dark colour, the woodwork is better painted white, as a contrast is essential to give relief and the proper effect. Many plants can be grown with success on such trellis, but one must be guided by the aspect of the site and the wall space available. The evergreen foliage of many wall plants looks very graceful on a suitable background and relieves the monotony of a bare wall. Well designed entrance gates also make a vast difference to the appearance of a house, and whenever you are ordering a new one give preference to something original. Simplicity of design, consistent with strength, often gives more pleasing results than something unnecessarily ornamental. A solid oak gate with an appropriate name-plate that is in harmony with its surroundings always suggests good taste of the owner and helps to form a dignified and artistic entrance.

Once inside the gate, the first thing that strikes one is the condition of the forecourt. If this is badly drained and, consequently, full of puddles, no matter how attractive the other part of the garden may be the pathway seems to engage most attention. Forecourts are, of course, constructed in various ways, according to the size and style of the house. If, however, it can be carried out in some quaint design in brick or stone flags, even if only a centre walk, with clean gravel on either side, a good dry path is ensured and a good effect produced, besides giving impression and tone to the whole lay-out.

GEO. W. HALL.

JAPANESE MAPLES WORTH PLANTING

WHEN planting trees in a small garden, a careful selection has to be made, mainly because, in a restricted space, comparatively small-growing specimens are desired with the maximum attractiveness and beauty. During the last fifty years a large number of acers, or maples, have reached our gardens from Japan; some of these are of great beauty, and now that they are thoroughly acclimatised they grow as readily, if not so rampantly, as the only native species. Neat and pretty at all times, they seem to us specially attractive when the buds open out in spring, and again when they assume their autumn colours at the end of the season; some species take on very pretty tints at the latter time—yellow, orange, brown and red predominating. We ought to say here that, opening out as they do early in the year, they must not grow on a site too freely exposed to cold winds at that time; nevertheless, they do best in an open site when not crowded out by other things. When once in growth they need no more attention than is given to other trees.

A Selection of Varieties.

Acer japonicum, in varieties, is commonly offered by nurseries; the leaves are large, green and with shallow segments. Two very fine varieties of this are commonly seen—macrophyllum, with small dainty foliage, and vitifolium, with spreading lobes, fanlike in appearance. Aureum, a sub-species, has golden foliage, of circular shape; laciniatum is much more deeply lobed and the segments narrower, a very pretty kind also. More popular than japonicum are the varieties of palmatum which are common everywhere, both in pots and in the open. The type itself has seven lobes; the varieties are badly named, however, no fixed rule being apparent in their nomenclature. Among the best are roseum (margined pink), septemlobum, dissectum (very finely cut up), atro-dissectum (dark maroon, variegated white), atro-purpureum (deep maroon, drooping), atro-purpureum variegatum (maroon on crimson), involutum (too delicate for the open), Aochun-shiki (green, variegated yellow) and others. Many other species and varieties are offered nowadays; it is impossible to distinguish them in popular notes—they have to be seen to be known—but among the best are reticulatum (netted yellow), scolopendrifolium (narrow, red lobes), Tsumagaki (green, tipped brown), versicolor (red, variegated green and white), Oshin-beni (small maroon leaves), pictum album (white variegated), filicifolium (fern-leaved), etc. An odd firm offers one or other of two really Japanese curiosities—Megane, in which two stems are trained into some open shape and four different varieties grafted on these; or Dantaiga, a plain shrub consisting of several kinds grafted on a common stock; personally, I do not like this, but they are real curiosities. Seeds of the more common sorts are sold, but, I am afraid, not in small packets. Occasionally the markets are overwhelmed with stocks of these Japanese maples from Holland and Germany at this time, and fine specimens can be obtained quite reasonably—CLYDESDALE.

Digitized by Google

THE ROCK GARDEN

The Beginner's Small Rock Garden.

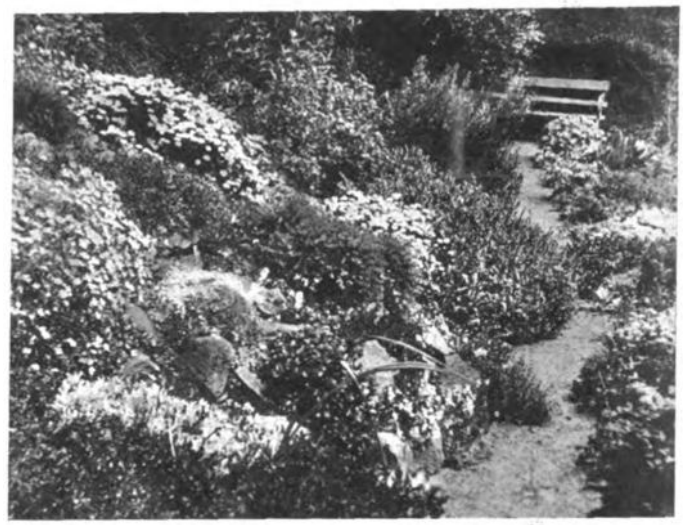
THE chief difficulty about the very small rock garden is the unequal rate of growth of the different plants, in consequence of which the smaller are often smothered by the larger. On sloping ground plants spread downwards much more rapidly than upwards, so a first rule is to plant the larger things below and the smaller things higher up. What are these larger things? Many of the most showy of the rock plants are too vigorous for the really small rock garden and should either not be used at all, or, if used, planted at the base of the slope, where they can expend their energy in spreading over the adjoining grass or path without doing any harm. In this category come Arabis albida, Alyssum saxatile and Aubrietia deltoidea and their many varieties—all grand showy things, but dangerous where space is very limited. To these must be added most of the mossy saxifrages and rock roses, and the larger pinks, etc. This is rather horrifying, as the plants mentioned are among the easiest and brightest of all rock plants; but a word of warning regarding them is necessary where the very small rock garden is concerned. Other plants which, though excellent, are a bit large and smothery for our present purpose, are Lithospermum intermedium, Othonnopsis cheirifolia, Polygonum Brunonis. I mention only one or two examples.

Small Sized Plants.

Now for a short selection of plants of more reasonable size, which will give a fair variety as regards flower, foliage, habit and time of flowering. The smaller achilleas are valuable on account both of their white flowers and their grey foliage. A. argentea and A. umbellata are among the best. Artemisia sericea and A. pedemontana have lovely silvery foliage, though their bloom is inconspicuous. Androsace sarmentosa and A. lanuginosa are the easiest of their charming genus. Armeria maritima Laucheana is a charming dark red sea pink. The aubrietias are too precious to be entirely excluded, but care should be taken to get some of the less rampant forms, such as Fire King. Small campanulas of course, we must have, such as garganica, Portenschlagiana, pusilla and the precious pulla. Then the erodiums are very pleasing plants with a long flowering period; E. Manescavi is somewhat large, and E. trichomanefolium or E. macradenum is more suitable. A bit of "Gentianella" (Gentiana acaulis) is, of course, indispensable, but it may or may not flourish with you. One of the orange-scarlet geums, G. Heldreichii or G. Borisii, adds a touch of vivid colour. Then there are the invaluable phloxes (P. subulata vars)—inclined to ramp a bit, but easily restrained and furnishing lovely sheets of white, lilac and pink. The smaller potentillas are neat growers, P. nitida being a particularly choice thing.

Stonecrops Worth Growing.

Sempervivums, with their little spiny rosettes are neat and characteristic. There is little use in recommending them by name, for in gardens the names are in hopeless confusion, but two of the best, which are usually correctly named, are S. calcareum and S. arachnoideum. Some of the sedums are neat and showy and unlike some of their kind, do not spread unduly; such are, for instance, S. Ewersii, S. kamtschaticum (which has an attractive variegated variety), S. Sieboldii, S. Ellacombianum. Silene Schafta is especially valuable because it flowers in August, when the rock garden is inclined to be very dull. The pinks are by no means all spreaders; Dianthus carthusianorum, D. sylvestris and D. neglectus are very well behaved and each has its own charm. Then Hypericum Coris and H. olympicum make neat little bushes which at flowering time are a sheet of gold. Blue is always a precious colour in the garden, and here the phyteumas help out the campanulas; P. hemispherica and P. Scheuchzeri are pleasant and neat. A delightful subject for any dry crack is Villadenia triloba, otherwise known as Erigeron mucronatus; it forms a little bush covered with pink and white daisies which continue from spring until autumn frosts put an end for the season to its activities.



AN ATTRACTIVE ROCK GARDEN PATH, UNOBTRUSIVE AND IN KEEPING WITH THE SIZE AND DESIGN OF THE GARDEN.

Dwarf Shrubs.

Most rock garden shrubs are rather too vigorous for the very small rock garden, but if a few are desired, the following will give a great variety of habit and colour. Cytisus Beanii, Hedera Helix vars. conglomerata and minima (two very quaint dwarf ivies), Juniperus communis compressa (a regular Noah's Ark tree), Spiræa Hacquetii and S. decumbens, and Veronica Bidwillii.

R. LLOYD PRAEGER.

(To be continued.)

ONE OF THE EASIEST AND MOST CHARMING OF THE ANDROSACES, A. SARMENTOSA.

Rock Garden Paths.

AN important feature of the rock garden is its paths: so important that a well made and beautifully furnished rock garden may be greatly marred by the ill designed or otherwise unsuitable paths which serve it. Here I do not propose to decide what such a path should be like in all cases, for so much depends upon the scope of the rock garden and other incidents. But in making a few suggestions I would first of all advise the novice on the look-out for guidance to be careful to avoid making the width of his walks out of proportion to the area he is concerned with. Where the rock garden is quite a moderate affair, a mere track of stepping-stones, such as in larger gardens may be used to link up the main walks, is often enough. But even when we come to more spacious areas I would always prefer to err to the narrow side in making the paths.

In the illustration the belt of rock garden to the left of the path is 10–15ft. wide, that on the other being much narrower. Here the path shown originally averaged about 2ft. in width, but the plants, which have encroached in a pleasing, natural manner from both sides, have so reduced it that it now does not average more than 1ft. That, in my opinion, is ample. It serves its purpose, it is in keeping with its surroundings, and strikes the eye as an attractive yet unobtrusive part of the whole.

Digitized by Google

This path, it will be noted, runs almost straight. This was decided by the nature of the ground, no other way being practicable. But there is no reason why such a path should not be more or less straight, the ground being level. Indeed, a good many reasons might be given by way of showing that a path which winds and wiggles to no purpose may be anything but right and appropriate. The path's first duty is to "get there" in the easiest possible way consistent with its environment. Take the sheep-track on a moor as an object lesson. Such a track has a definite objective, and, while its course is, from point to point, straight, it only bends this way or that to avoid an outcrop of rock or a hummock of heather. Thus we have a path which justifies itself in every detail in so far as lay-out is concerned. Should the rock garden have a steep pitch, then, of course, your path, following the line of least resistance, would take a circuitous route so as to ease the grade, and in this instance again the sheep track is a reliable guide.

It is not necessary to state here that a formal edging of plant or stone is altogether out of place in the rock garden proper. Plant and boulder must always unite in forming a bordering so natural and diverse that the line where the rock garden ends and the path begins is practically imperceptible.

One word as to the surfacing of the path. Here, again, much will be decided by the conditions, but in a general way my own preference leans towards the path which is constructed as nearly as possible of the same material as the rock garden itself. That is to say, it may be of coarse gravel or stony soil beaten firm, with here and there a few inlaid stones to break the uniformity. If weeds or dampness are troublesome this surface may be covered with fine gravel or grit if something soft to the feet can be procured; but if there is one thing I heartily abhor in a path of this sort it is granite or flint chips, which crunch and grind like granulated sugar under one's feet. I would rather have a plain, hard earth path than that; and when this is partly or wholly covered by such plants as thymes, cotulas and the like, there is something to be said for the idea. Inlaid flat stones, as I have suggested, are not to be despised, whether placed as stepping-stones or dropped in, as it were, by accident; but paving of any manifestly artificial sort, especially when "crazy," should be *taboo*. Something of this nature may be advantageous in conjunction with the small rock garden of a suburban villa which constitutes a part only of the garden, but even here I would rather have old porous bricks laid in than slabs.

A. T. JOHNSON.

ORCHIDS OF EASY CULTIVATION

CYMBIDIUMS have much to recommend them; their freedom of flowering and good constitution render them especially suitable for an ordinary greenhouse in which a minimum temperature of 50° can be maintained. If the temperature should fall a little below this figure, the plants will take no harm provided that rational treatment in other respects is the order of the day.

General Culture.

The plants succeed in ordinary pots large enough to accommodate the occupant comfortably, but over-potting must be guarded against. It must be realised from the start that cymbidiums are terrestrial plants like the majority of the cypripediums, and as distinct from the great majority of orchids, therefore it will be readily understood that terrestrial orchids require a very different rooting medium from the epiphytes, one with more "body" in it, for they do not obtain the same amount of sustenance from the atmosphere as do dwellers in trees.

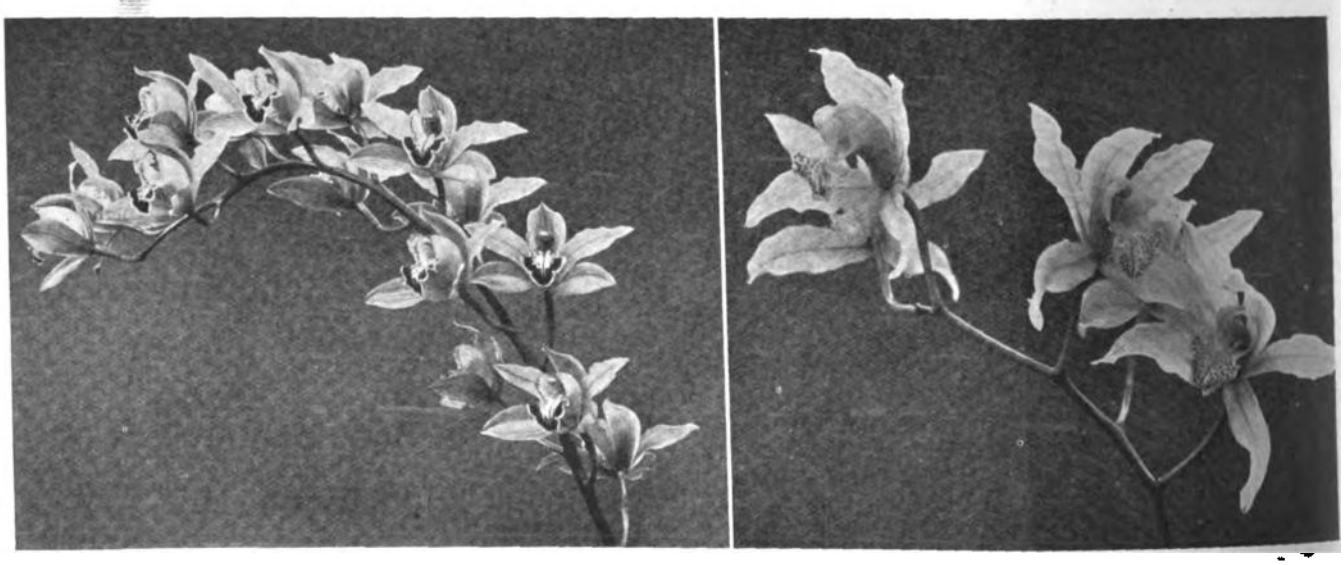
A good compost for cymbidiums is three parts fibrous loam to one part osmunda fibre or good orchid peat, the former for preference. To this should be added a few crushed crocks, some sharp sand, a few nodules of charcoal and some sphagnum moss. The pots should also be surfaced with a few live heads of the latter. The surface moss is a great help in watering, for should it take on a white and dried appearance it is a sure indication that the plant requires water.

The drainage of the pots must be perfect, and rather more "crocks" should be used than for most plants.

Moisture and Ventilation.

Careful watering is one of the essentials to successful culture. An intelligent study of the plants themselves will lead to good watering, and it is well to remember that the plants are far happier when on the "dry" side than when they have their roots surrounded by soddened soil, a condition leading to rotten roots and inevitable ill-health.

Atmospheric moisture, supplied by damping down the paths and other surfaces of the structure and by syringing between and over the plants, must be applied in quantities to coincide with the outside weather conditions, knowledge which ordinary intelligence will readily supply. The same remarks apply to ventilation, and here it may be well to state that orchids, and more especially cymbidiums, do not enjoy a stuffy atmosphere. They require, and must have, an abundance of fresh air, supplied intelligently and chiefly from the top of the house. Side ventilators must be used with the utmost care, for cold draughts are harmful. There is no set season for potting, but as the majority of cymbidiums flower in early spring and summer, and as the most suitable time for re-potting is soon after flowering, the greater part of the work will become due during the spring—April and May. Here it should be stated that annual repotting is not always required, nor is it always advisable. The plant will tell you when it is ready. In plain, everyday language, when the growths have reached the edge of the pot, it will require a little more room but not too much, for cymbidiums do not flower so well if the root-run is too generous.



CYMBIDIUMS PROVIDE MOST ATTRACTIVE FLOWERING SPRAYS FOR GREENHOUSE DECORATION.

Species to Grow.

The species should most certainly be grown, and in Lowianum, giganteum, Traceyanum, eburneum and insigne we have some superlatively good plants. The present-day interest in cymbidiums, however, lies in the host of lovely hybrids obtained from these old species. Their number is legion, their forms and colours are such as to appeal to all tastes. There are pink and red shades, yellows, greens, browns and whites, but almost all possess the arched spike and long grass-like foliage, the attributes of a great decorative plant.

Some of these hybrids are expensive, others are reasonable; some, again, are comparatively cheap, and my advice to a prospective grower is to visit the establishment of any well known orchid firm when the plants are in flower and to make a point of seeing some of the exhibits at the leading shows. "To see is to believe," and is better than any stereotyped description.

RALPH E. ARNOLD.

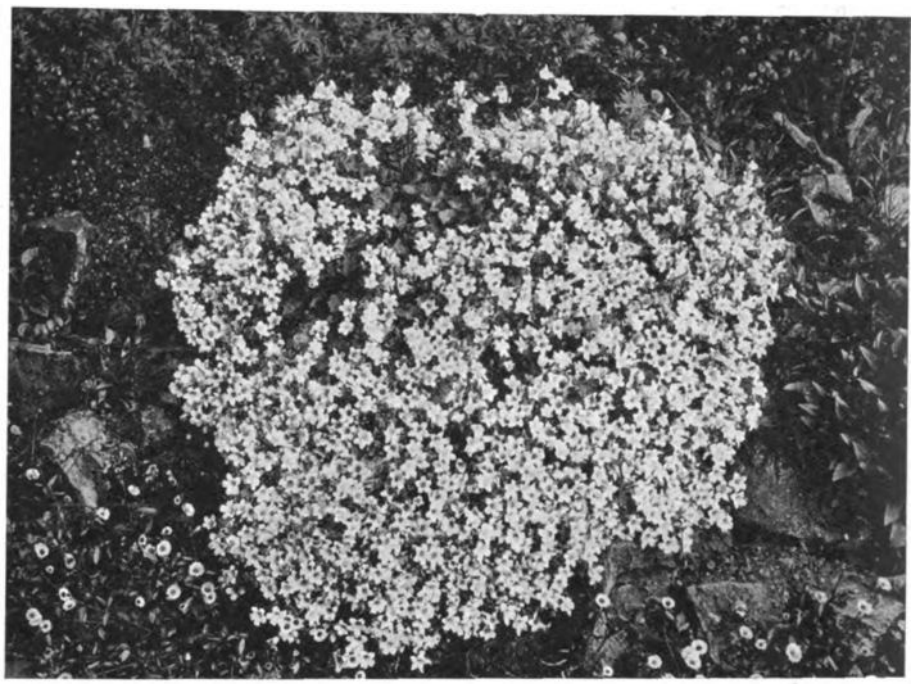
BELL FLOWERS FOR THE GARDEN

A FEW GOOD BORDER VARIETIES.

THE family of campanulas is a large one and among the host of good things will be found several suitable for the herbaceous border. One of the best is C. persicifolia, the peach-leaved bellflower, which grows about 2ft. high. The blue flowers, which are large and somewhat flat, are produced in long spikes, which make them valuable as cut blooms, while for embellishing the flower garden they are in the front rank. There is also a white variety which is even more desirable than the type. The different forms have all the characteristics of C. persicifolia except the flowers, and in the case of Moerheimii, they are semi-double and white, and this must be put down as one of the best. A counterpart of this is humosa, a semi-double blue. This is a decided acquisition and both grow about 2½ft. in height. A giant among the peach-leaf harebells is the grand Telham Beauty; the plants when well grown reach 3ft. to 4ft. in height, having long, wiry stems which are clothed with large, bell-shaped flowers of delightful pale china blue. This plant does not require staking, a remark which applies to most if not all of the persicifolia section. The Lissadell variety is another gem, with beautiful silvery lilac blossoms, freely produced. Another form with light lilac flowers is Fairy Queen.

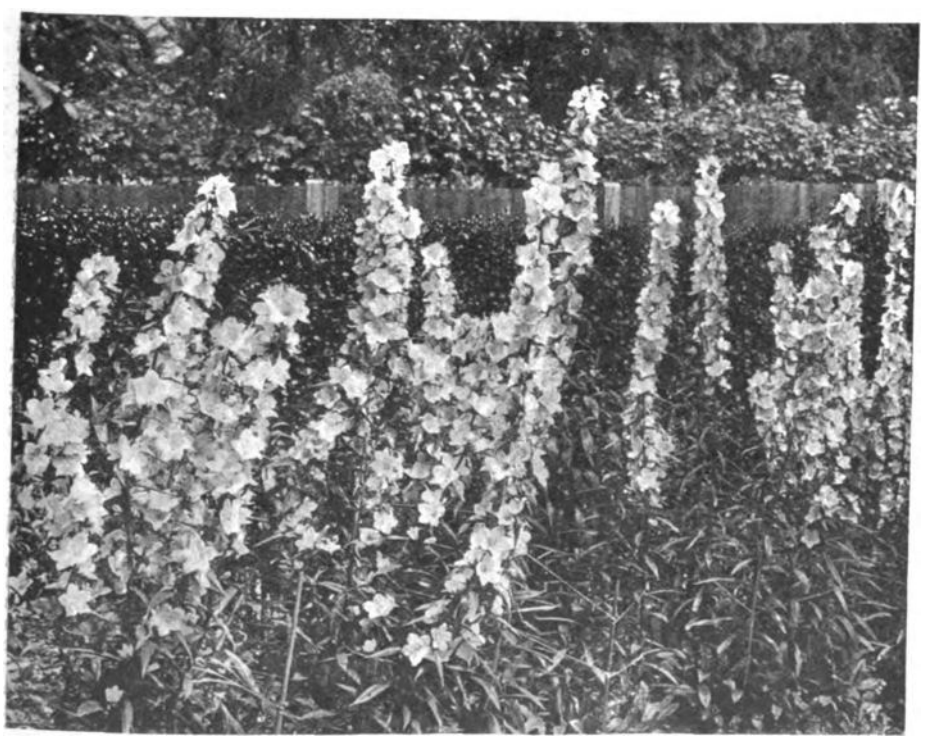
All those mentioned are excellent garden plants, easily grown and will afford a maximum of beauty from June to September, with a minimum of trouble. Another point in their favour, they are not aggressive, and will not encroach on their neighbours, but to keep them in fine fettle, division must be resorted to about every third year, and this is best accomplished at this season. Another method is to take cuttings of the side shoots immediately after flowering, growing them in a spare piece of ground until the following planting season. An interesting and profitable pastime is raising seedlings of C. persicifolia. A packet of seed will produce a quantity of healthy plants of average merit.



A TUFT OF CAMPANULA PORTENSCHLAGIANA IN THE ROCK GARDEN.

Other Tall Campanulas.

ALL the peach-leaved campanulas should be supported by branching twigs inserted among the flower-stems before they exceed a few inches in height. Campanula latiloba (syn. grandis) was a greater favourite in the past than it is at present, and few old gardens are without big clumps of it. It is not as attractive as persicifolia and its tendency to spread about makes it something of a nuisance, but it is a useful plant for semi-shade. Campanula glomerata is a worse sinner in the matter of encroaching than C. latiloba, but its masses of deep violet flower-heads on their sturdy 2ft. stems are beautiful in sunshine. One of the most effective of all the border campanulas is lactiflora, which grows 4ft. or more in height and produces quantities of big, loose panicles of flowers. In the type these are pale, milky lavender, but there is a variety of a deeper colour as well as a white one. C. latifolia is also good in the border. Its height is about 3ft. and its colour a deep lavender, but it is not very happy in soil containing much lime. The bell-shaped flowers of the seldom-seen C. alliarefolia are of a rather dingy white, but the plant is worth growing if a damp, slightly shaded place is available. It is intolerant of drought, and will be stunted and miserable-looking unless it has moisture at the root. The garden varieties of our native harebell, C. rotundifolius, are tall enough for the border, and their delicate blue is very pretty. In sharp contrast to the fragile little harebell is the chimney campanula, C. pyramidalis, with splendid lavender-blue or white spikes.



CAMPANULAS ARE ALWAYS USEFUL IN THE BORDER. THEY ARE TALL, GRACEFUL AND FULL OF FLOWER.

A Rock Garden Campanula.

IN spite of its long name (C. Portenschlagiana) this is an old and pretty plant, generally met with in gardens as C. muralis. It is an excellent subject for the rock garden, where it can be allowed to cover a large stone, while for retaining walls it has no equal. Along the front of a border it is quite at home, in fact there are a lot of places where this common plant would thrive and be a joy to the owner throughout the summer months. Of a trailing habit, the plants are free flowering, the light blue-purple blossoms being erect or nearly so, stand well above the exquisite small leaves.—T. W. B.

THE FLOWER GARDEN

The Globe Daisies.

THE globularias are a small genus of evergreen—almost sub-shrubby—alpines which, if not among the most showy, are certainly of more than average interest on the rock garden. The species generally met with is G. cordifolia, of compact prostrate habit, with numerous heads of pretty blue flowers. It forms a dense carpet and attains a height of about 3ins., the small glabrous leaves are spoon-shaped, and a well grown plant will be covered with flower-heads in May and June. There are two somewhat rare varieties, *viz.*, alba with white flowers, and rosea, a pink-flowered form a counterpart of the type except colour.

The true G. nana is the smallest of all. It is found growing on the sunny face of the rocks in the Pyrenees, and this gives a clue to its requirements in this country. It is a pretty subject for covering stones, where it forms a thick carpet about an inch high. The lavender heads of flowers are produced from May to August.

G. incanescens has beautiful grey-blue foliage, and is less rampant than G. cordifolia, which warrants it a choicer position on the rock garden. It hails from the Pennine Alps, and forms compact tufts of small leaves, with heads of blue flowers.

G. vulgaris is freer in growth than many of the species, and produces globular heads of pale blue flowers, while G. trichonantha has long, shiny foliage and balls of blue flowers. The latter is tufted and somewhat shrubby in habit.

All the kinds can be increased by seeds, division of the larger carpets and by layers. The globularias are well worth consideration from the rock gardener, and a mass of G. cordifolia several feet square with its myriads of fluffy, globular heads of blue flowers is, indeed, a glorious sight, and is one that will compel admiration from all flower-lovers. They all enjoy the sunshine, although they will succeed in partial shade, neither do they object to a rather dry position. There are many places on the rock garden where they would find a congenial home nestling against some warm stone with a rooting medium of loam, leaf-mould and grit. Lime rubble may be added with advantage, because they are often found growing wild on calcareous formations.

T. W. B.

ONE OF THE BEST OF THE GLOBE DAISIES, GLOBULARIA INCANESCENS.

The Christmas Daisy.

THIS is the very latest of all the asters (A. grandiflorus) to flower—hence its name of Christmas daisy—and, unfortunately, though perfectly hardy, its flowers are often spoilt by frost while still in bud. For this reason it is not very popular; but when the season is sufficiently favourable to permit it to bloom it is so attractive that it makes amends for many disappointments. It forms a sturdy, compact little bush 2½–3ft. in height, and its flowers, which are fairly large, are a rich violet-purple in colour. They are admirable for cutting, as they last a long time in water. The Christmas daisy should be given the most sheltered spot available, against a south wall for choice, and at the first indication of anything approaching a severe frost it should be screened by a light awning of thin canvas or some similar material stretched on bamboos. The roots need no protection.—R. E.

Preparing for Next Year's Annuals Indoors and Out.

ANNUALS, both hardy and half-hardy, occupy much space in our gardens in these times, and rightly so, for they are inexpensive and yield sheaves of flowers over a very long period if properly treated. We should take just as much trouble with the annuals as we do with our roses, carnations and chrysanthemums, because they deserve it. It is because annuals can be so easily grown that they are, to some extent, neglected. There is a vast difference between the plants carelessly grown and those really cultivated. Many persons take much pride in growing fine asters and many fail to grow them satisfactorily because the plants die suddenly just when they reach the flowering stage; many also die in their seedling stage. It is a fungus that causes the mischief. Now, growers should obtain some good fibrous loam at once and sterilise it by burning. This can be easily done by making a trench on sloping ground 1ft. wide and 1ft. deep. Place a sheet of iron over the trench, light a fire at lower end and thoroughly heat thin layers of compost placed on the iron sheet. Then store the compost in a cool, dry shed until it is required in spring for the seed-sowing. The plot of ground in which the asters are to be planted next summer should be well limed now. Of course, the sterilised compost will be available for sowing seeds of stocks, clarkias, zinnias, larkspurs, lavateras and other annuals in boxes and pots in spring. All annuals now in boxes or in frames should be guarded against excessive damp, as their tender stems soon succumb to it. Where rotted manure will not be available for the summer planting, as much leaf-soil and decayed vegetable matter as possible should be collected during the winter, turned from time to time with sprinklings of lime put on while doing this, so that the whole mass will be in the right condition for digging into the borders in April. Boxes in which seedlings are to be raised in should be lime-washed now, then stored in a dry shed until required.—G. GARNER.

An Attractive Daphne.

DAPHNE BLAGAYANA is one of the most delightful of small creeping shrubs for the rock garden. It is not showy, it is true, nor has it the attractions of D. Cneorum or D. rupestris, but it has charms of its own which they cannot share. No one of the other daphnes named can serve as a substitute for D. Blagayana, nor, for that matter, can it take the place of the others. It stands by itself, a low, creeping shrub, delighting to send its branchlets among the stones and giving us among them the fragrant, creamy white flowers in early spring. So far as sun or shade goes, it does not appear to mind, but it must have stones about it, and the best plants I have ever seen have been treated to what, by a stretch of the imagination, might be called a "mulch" of stones, among which it can ramble, and whose coolness would seem to afford health and vigour to this attractive plant. Although a native of limestone regions, where it rambles in the screes, or moraines, yet it does not demand that the stones we may pile on it should be limestone. Any other will do as well, but if happiness, health and floriferousness are demanded the stones must be supplied. As the plant grows, heap on the stones and the reward will be great and satisfying. Then the branches will root into any soil between the stones, and can be cut off and planted apart when increase is wanted. The soil may be of peat or loam, but it should have plenty of stones.—S. ARNOTT.

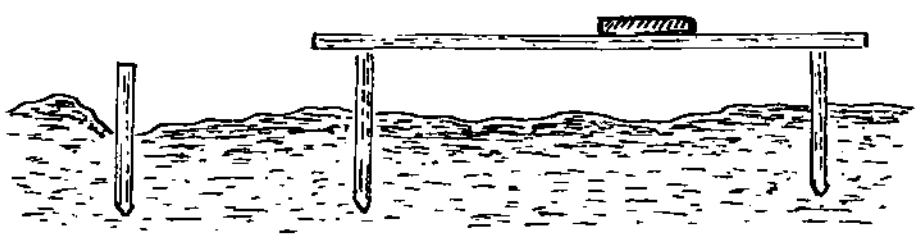
THE BUSY MAN'S PAGE

The Birds and the Fruit Trees.

FROM the end of December and onwards into the New Year fruit growers' troubles commence with respect to birds. Long before there is any sign of movement on the part of the gooseberries, red currants, pears and plums they attract the attentions of certain birds, especially bullfinches, which, by the way, are far more common in many districts than is often supposed. Evidence of destruction is seen in the remnants of buds which are found strewn under trees and bushes. To prevent the serious destruction of the buds there is, perhaps, no better way than to syringe the branches with soapy water and, while the buds are still wet, dust lime or soot on to them. This makes the buds distasteful to the birds; but, in the case of large trees of plum and pear, the application would be a somewhat difficult matter. Here the birds may be scared away by tying some fluttering rags in various parts of the tree. If the rags can be of blue cloth so much the better. Some tests which have been carried out show that birds have a great dislike to the colour blue. Although the fact is well established, the reason why birds avoid blue is quite unknown. It is well, in the case of currants and gooseberries, to delay the pruning for as long a time as possible.

Simple Ways of Levelling Ground

WHEN the piece of ground is comparatively small and it is merely a question of levelling after rough digging, there is nothing so handy as a rake. If the area is considerable and the land is naturally uneven at the start, it is needful to adopt a more reliable method of securing a uniform surface. Practically any area which is likely to be met with in an ordinary garden can be levelled with the use of pegs. Each peg should be about a foot or 15ins. in length, with a good point at one end. Start by hammering a peg into the soil for three-quarters of its length at some place where the desired level of the surface can be easily obtained. A starting point can often be found in the base of a house or wall. Now drive another peg into the ground 6ft. from the first and rest across the top of the pegs a long strip of wood on its edge. By placing a spirit level on the top of this, one can soon determine whether the tops of the pegs are level. Where a proper spirit level is not available quite a good substitute is found in a small narrow bottle. This should be not quite filled with water, and then, when the bottle is corked and placed on its side, the air bubble will give indications of the level, or otherwise, of the surface. If the tops of the pegs are not level it is a simple matter to hammer them down until the right position is secured. Another peg is now driven into the ground about 6ft. away and the levelling process between this and one or other of the first two pegs is carried out. Eventually a series of pegs will have been driven into the ground at regular intervals, the tops of which are all level. The ground, which has been previously dug to a suitable depth, is then worked up until all the pegs stand up to an equal height above the ground. As an example, if the first peg is 4ins. above the soil, then the others may be marked as a guide to the adjustment of the level.



HOW TO OBTAIN ACCURACY IN LEVELLING.

When Ferns Get Too Large.

THERE are two aspects of an outdoor fern —both ornamental. One concerns the young and small stage and the other the established plant of great age. When young, ferns of any kind are useful on the rockery and in odd shady corners, but it needs a large space and woodland conditions to accommodate large ferns; the latter, therefore, often become unsuited to the garden and cover too much space with their enormous fronds.

When this state becomes imminent, the large roots should be lifted from their places in the autumn. It will then be seen that some portion of the root-stock is no longer contributing to the health of the plant, and may be cut away entirely. Then it will be noticed that there are two or more distinct divisions in the root, each having a group of embryo fronds. These sections should be pulled apart, roots being carefully retained in all cases, and these will form new plants, greatly reduced in size, and may be replanted as such. By this means, ferns can be kept to reasonable size, at the same time giving a welcome increase of stock.

Growing the Christmas Tree.

OFTEN the question arises whether the neat little spruce fir which has helped so much in the Christmas festivities is worth planting in the garden. Everything depends on the condition of the root stock which is attached to the tree. If, as sometimes happens, practically all the roots have been cut away, it is only waste of time to try to grow the tree. When the grower has lifted the tree with a fair amount of roots attached there is no reason at all why, with a little care, the young spruce should not be established. Much depends on the proper planting of the Christmas tree, for, if it is dumped down into ordinary garden soil, it probably will not succeed in getting a foothold. Open up a somewhat larger hole than is actually required and, except in very light soils, partially fill the opening with a mixture of sand and leaf-mould in equal parts. Where the soil is naturally light, leaf-mould should be worked into the ground to provide a suitable rooting medium. Tread the soil round the tree, firmly planting it to the depth indicated by the mark on the stem. Always give the fir support with a strong stake, as, without this, the tree is sure to rock about during rough weather and then there is very little chance of its ever becoming established.

The Value of Trenching.

TO maintain the fertility of soil, if crops of first quality be desired of either fruit, flowers or vegetables, it is essential that portions of ground be trenched or double dug annually to attain this object. No amount of manuring can equal deep cultivation, or act as a substitute. Trenching makes for freer drainage, the outlet of injurious acids and the inlet of light and air and the purification of the soil, and more food available to plants. A good layer of garden refuse such as weeds, leaves, pea haulm, stems of herbaceous plants, should be placed in the bottom of the trench, with a good dressing of manure or Wakeley's Hop Manure near the top spit. The conditions thus afforded of coolness and moisture, favourable to the vigorous and healthy root growth of plants, enables them to come through periods of summer droughts as good crops and little impaired.

DIVIDING LARGE FERN ROOTS. EACH SECTION WILL FORM A NEW PLANT.

Mistletoe: How to Grow It.

A PLANT of mistletoe is an interesting feature in the garden, and there is no evidence that it does any harm to its host, which is most commonly an apple tree. With a little care there is no reason why a plant of mistletoe should not be established on an apple tree. One very important point is that the seed should be properly matured before it is sown. The fruits are not ripe until the end of February, and the best way is to take a well berried sprig from the Christmas decorations and put this into a jar of water. Keep the whole thing in a cool light room and change the water every week or ten days. The berries will then ripen as well as if they were attached to the growing plant. When the time comes for sowing the seed select a clean young branch on an apple tree. Then a few of the berries may be rubbed on to the underside of the branch where there is little risk of the seeds being eaten by birds or washed away during rain. No cut of any sort is required, and the seeds will adhere by means of the glutinous substance with which they are surrounded. During the first season only two green cotyledons or seed leaves are produced. Even the second year growth is comparatively slow; but when once the plant is really established, mistletoe grows rapidly and it may be cut freely when required. It is well to get several seedlings established, as the male and female flowers are on different plants and, naturally, it is only the latter which will produce berries.

FLOWERING SHRUBS for HOUSE DECORATION

Where a small greenhouse is available, all amateurs should undertake the forcing of a few suitable flowering shrubs such as those suggested in the following article. They provide a most attractive display of blossom at a period when colour is lacking for interior decoration.

AT this season of the year there is often a difficulty in keeping up a display of flowers for the decoration of the house and conservatory. In the following list will be found shrubs that may very easily be brought into flower with but little expense of fire-heat, providing they are properly cared for and well set with buds. Among the shrubs enumerated will be found a great variety of colour in the flowers, also an adaptability of shape and form to suit even the most exacting of tastes.

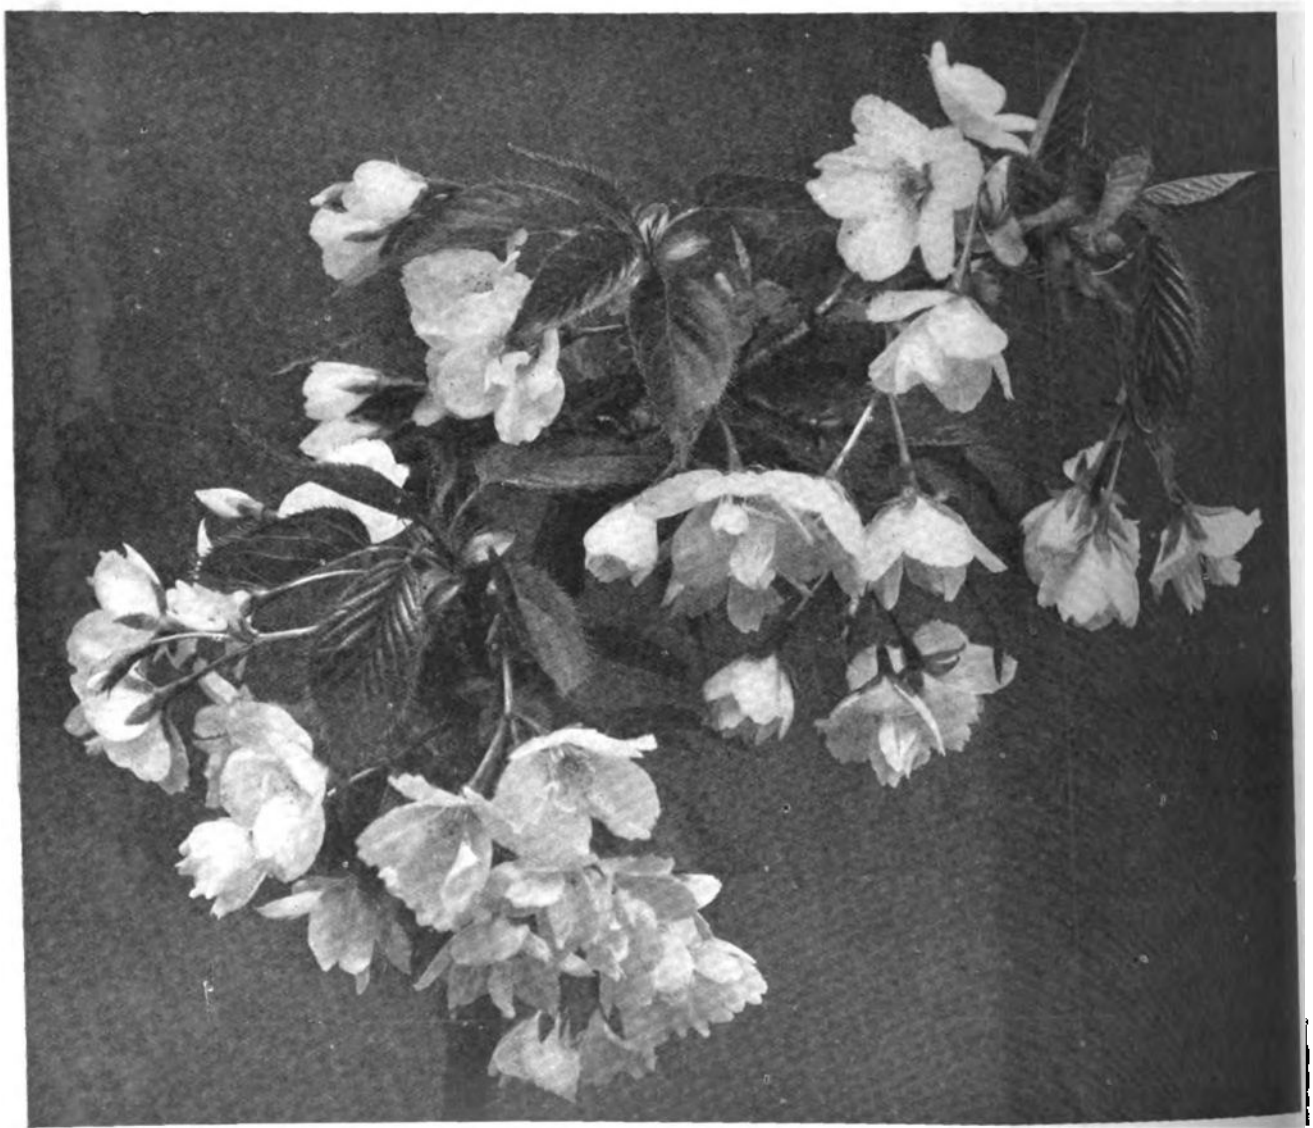
and Rosa Mundii. This latter is a grand variety for early work, being compact in growth and of a pleasant shade of colour, also exceptionally early. R. Cunningham's White and many others.

Prunus in variety.—P. triloba fl. pl., double rose, P. sinensis fl. pl. alba, and rosea pleno, are a trio especially useful for 6in. and 8in. pots for furnishing, being erect in habit of growth. The double cherries, Cerasus Pseudo-cerasus, James H. Veitch, double rose; C. serrulata, double white; and other varieties.

Viburnums plicatum and the newer Carlesii, that is very sweetly scented, are always attractive in flower.

Some of the dwarf forms of philadelphus, such as Lemonei hybrids, are very free flowering. Virginale, Bouquet Blanche and Avalanche are three good ones.

A few standards of Wistaria sinensis interspersed here and there are always effective in the grouping arrangement. The same may be said of plants of Acer Negundo variegata, A. palmatum sanguineum and



A SPRAY OF PRUNUS SERRULATA, THE JAPANESE CHERRY, WHICH IS OBTAINABLE IN MANY FINE FORMS AND MAKES A MOST EFFECTIVE DECORATION INSIDE AND OUT.

Previous to taking the various shrubs in for forcing, the plants should be cleansed, pots washed and top-dressed, if required, arranging them on inverted pots or tiles, thus keeping them clear of the soil. See that plants do not come in contact with others already in the greenhouse. Spray over with tepid water several times daily during bright weather, also use tepid water at the roots whenever required; this is an important point to remember when forcing.

Growth will soon be active in the case of such shrubs as Spiræa Thunbergii, S. arguta multiflora and S. prunifolia fl. pl., the double form, Rhododendrons præcox

Magnolia stellata, white, one of the best for this purpose, dwarf and compact; M. conspicua, M. Soulangeana, etc.

Syringas (lilac).—Charles X, rosy purple; Marie Legray, white; including Mme. Lemoine, double white, are three good sorts.

Forsythias add a touch of gold in colour of flower, F. suspensa being of pendent style of growth, while viridissima assumes a more erect form.

Deutzias, such as gracilis, corymbiflora in various sizes are very useful and largely grown; and Staphylla colchica, with white fragrant flowers, is always appreciated.

other varieties of acer. These add considerably to the effect, and may be easily had in full foliage under the same treatment as for flowering shrubs.

Hydrangeas may easily be brought forward into flower, especially H. hortensis and Mme. Moullière, white, one of the best and probably the most floriferous of all.

Azalea mollis in variety.—These are well known and appreciated by all both as pot plants and for cutting purposes.

With such a variety of easily forced plants enumerated there need be no lack of flowers during the early months of the year. While the plants are in full flower, in the event

Digitized by Google

of bright sunny periods, it will be found advantageous to run the lath-roller blinds down. Of recent years these blinds are used in winter as protection during severe frost, and are retained in position. This being so, they are always available when required. Shading from bursts of sunshine certainly preserves the flowers.

Cultural Notes.

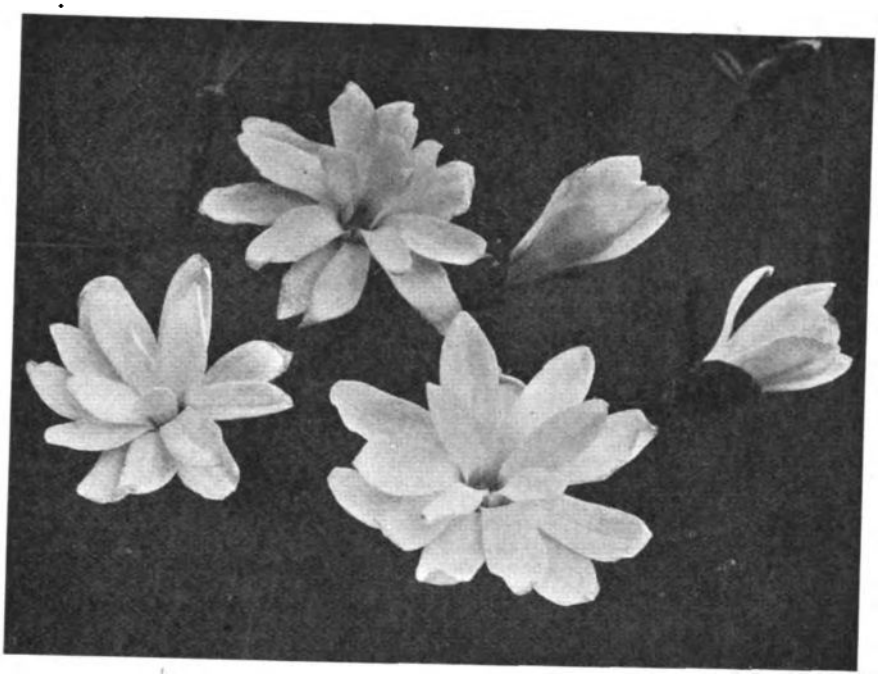
A few cultural notes on the subject may be of interest. After the plants have finished flowering they must be hardened off before being placed in the open, where they should be encouraged to make their growth *early* for another season's work. All dead flowers and seed pods being removed, prune back such subjects that require to be done, such as forsythias, spiræas, deutzias, etc. When growth is fairly active, pot on any that require larger pots and feed at intervals with liquid manure those requiring assistance. Plunge the pots in a bed of ashes in the frame ground during the summer months, giving due attention to syringing and watering, the supply of which should be reduced as the leaves change colour in the autumn months. When the plants in pots are standing outside in a bed of ashes, it should be seen that the ashes are tightly packed between the pots to prevent the roots of the plant and the pot itself from becoming unduly frozen. When the plants are taken from their outside positions they should be carefully introduced to a forcing temperature which is a mild one, varying from about 55° to 60° Fahr. Indeed, it is only in very exceptional cases, where rapid forcing is desired, that it will be found necessary to have a much higher temperature. A high temperature places too great a strain on the plants and leads to a rapid deterioration of the constitution and vigour of the plants, and should, therefore, be avoided.

The age of the shrub used for forcing must also be taken into consideration. Do not commence forcing a shrub into flower two or three years ahead of its time. That way disaster lies.

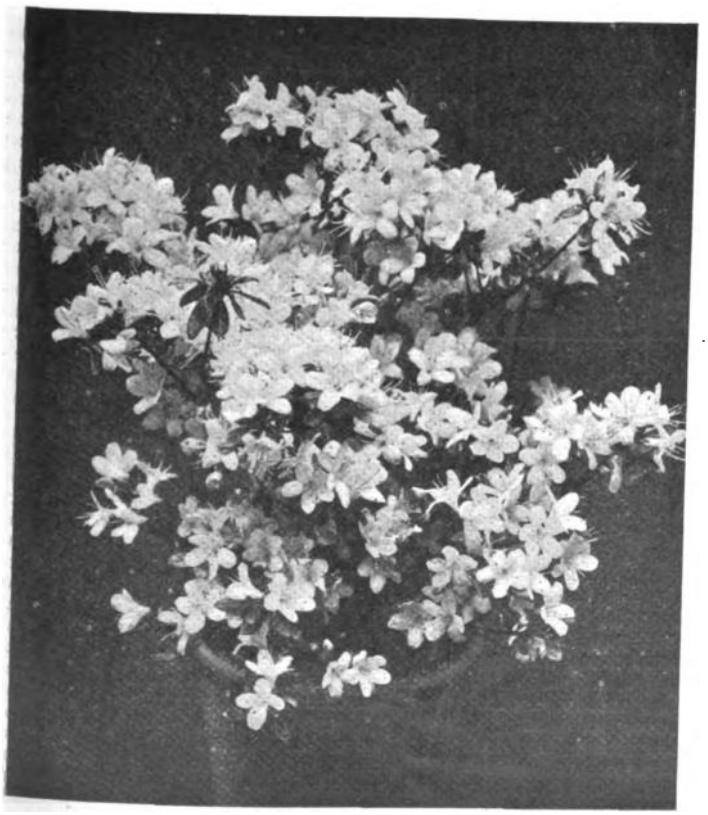
The ideal place for forcing shrubs is in a vinery or peach house where the atmosphere and temperature are both suitable. But as many gardeners do not possess a vinery it should be their aim to approximate to such conditions as closely as possible. If it is made certain that drainage is free and that the ball of soil is thoroughly moistened, then success is assured. Clear water must always be applied until the flowers have faded. The new shoots of the majority of these shrubs, especially azaleas and rhododendrons, appear as the buds develop and finish their growth almost by midsummer. Treated thus they will last many years. Should any become too large for the purpose required they may with advantage be planted in the shrubbery or beds where they will give a display for a number of years to come, smaller plants being grown on or procured to take their place.

The forcing of shrubs such as I have mentioned has much to commend it, especially so where a supply of flowers is required at probably the most difficult time of the year. Most of the shrubs may be obtained from nurserymen of repute who specialise in flowering shrubs that are now so popular in all gardens up and down the country.

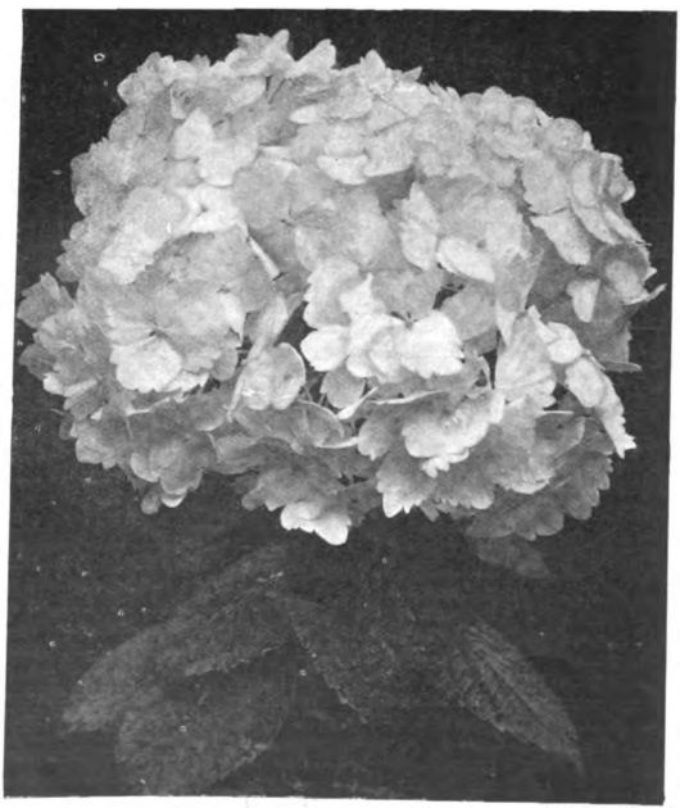
J. HAWKES.



MAGNOLIA STELLATA PROVIDES BEAUTIFUL BLOOMS BY FORCING.



NO SHRUB CARRIES MORE BLOSSOM THAN THE JAPANESE AZALEA.



THE LARGE WHITE HEAD OF HYDRANGEA MME. MOULLIERE

THE FRUIT AND KITCHEN GARDEN

Old Orchard Trees.

MANY of our old orchard trees yield—apples and pears mainly—when some of the younger and newer varieties fail. The fruits are mostly inferior, but still they are fruits and fill a gap sometimes. We want to go forward and not backward; we must replace old specimens with young ones, for, if we do not attend to this matter we go backwards—the old trees deteriorate. It is not always convenient, nor is it wise, to discard all old trees in an orchard at once without very good reason. I strongly advise cultivators to make their new orchards in other positions where this is possible. If, however, the old orchard must be retained, and practically all the old trees in it, a very close and careful examination of the latter should be made during the winter months. Observation in the summer should lead to action in the winter. Usually, our big old orchard trees only bear fruits near the tips of the branches, the main part of the interior of the tree being quite without fruits. Some very beneficial thinning-out of overcrowded branches may be done now; dead or dying branches, too, should be cut out and insect-infected trees dressed with tar-oil wash, which will, where it penetrates the bark, kill hiding pests and eggs. Having done something useful to the branches, deal with the roots forthwith. Grass growing right up to the stem of the tree is bad for the specimen and it should be cleared away quite 3ft. from the trunk all round. Simply free the soil from weeds and especially the tap-roots, if any, of coarse weeds. Then put on rotted, or half-rotted, manure and fibrous loam, mixed, to a depth of 3ins. Also pour in freely diluted liquid from the farmyard or from manure heaps. If soil and grass cannot be removed as here recommended, bore holes in the grass, 2ft. apart and covering the space where roots are likely to grow and pour liquid manure into them three times during the months of December, January and February. Old fruit trees are not fed much at any time.—G. G.

Currant and Gooseberry Cuttings.

THESE useful bush fruits are so easily raised from cuttings that everyone who possesses a garden should root a few each year to replace failures or old worn out bushes. Now is the time to make and insert these cuttings. Select strong, well ripened, current year's growth, avoiding the over-vigorous wood which is inclined to be sappy. The cuttings should be 10ins. or 12ins. in length and the base cut square with a sharp knife, just below a joint. Remove the unripened wood forming the tip of the shoot with a slanting cut.

In the case of red currants, white currants and gooseberries, all the buds except the top three should be carefully removed. This ensures that the resulting bushes will have a clean "leg" and that sucker growths will not spring from the base—an undesirable feature in the cases named. Black currants require a little different treatment, for here the fruit is produced on young wood and it is the object of the cultivator to encourage the growth of this type of wood from the base, therefore the buds in this case are not removed.

An open position sheltered from cold winds should be chosen for the cutting ground and this should be deeply dug and worked until a good tilth is obtained. No manure should be added, but if the ground has been manured well for the previous crop, so much the better. Open a clean trench 7ins. or 8ins. in depth and with the back wall cut slightly inclined. Against this wall the cuttings should rest at a distance of 4ins. apart and taking care that the bases of the cuttings are touching the bottom of the trench. If the soil is at all of a heavy nature it helps considerably if a layer of sand is sprinkled along the bottom of the trench before the cuttings are put in. A distance of 15ins. should be allowed between the rows. After insertion tread the ground firmly, but not too hard.

The treatment the cuttings require throughout the first year is not exacting. After severe frosts they should be examined and if they have been loosened by the action of the frost on the soil they will require treading firmly again. During the summer hoe frequently to encourage growth and keep down weeds, and in the following autumn, when the leaves have fallen, lift, prune them back and transplant on to a good piece of ground, allowing a distance of 1ft. between the plants and 18ins. between the rows. Do not plant too deeply, as if the roots are 4ins. or 5ins. below the surface it will be sufficient. The following autumn they will be ready for transplanting into their permanent quarters.

Many other plants may also be propagated in this way, including privets, forsythias, most roses, flowering currants, weigelas and many others.—T. H. EVERETT.

New Varieties of Potatoes.

GOOD new varieties of potatoes are always welcome and most gardeners are glad of a chance to add to their already well stocked collection. Really good varieties of merit which have been introduced within the last few years are very few indeed. Arran Consul, raised and introduced by Mr. Donald McKelvie Lamlash, is not yet so well known to growers as it ought to be. As a cropper it has far surpassed all the other newer varieties. The tuber may be described as a round-oval, although some are distinctly oval, still, quite a number will be found on the same plant that are almost round and often rather irregular in shape, many tubers growing far too large for exhibition purposes. Even allowing for the largeness of the tubers, I have never come across one with a hollow centre. The colour of the skin is white and the flesh slightly lemon. Growth and habit are excellent for garden purposes, being vigorous and upright, although slow in starting in spring, it grows into a bushy plant during summer, which tends to become spreading towards maturity. The leaflets are thick and leathery, somewhat resembling President in appearance, but much more crowded and produced closer on the leaf stalk. The chief feature of Arran Consul is its splendid keeping qualities. Growers will find it a most useful potato for storing, and it does not sprout readily in the pit. It is not affected in the least by blight, and being resistant to wart disease is one that can be recommended as a late variety for garden purposes.

Another of our recent Scottish introductions is South Esk (named "East Neuk" when put on the market). It is a most useful round late potato, and, like Arran Consul, is also a splendid variety for storing. The skin is white, but tends to become slightly purple round the heel end and eyes of the tuber on exposure, which might bar it as a white round on the exhibition table. The flesh is slightly lemon in colour, of excellent quality, cooking very dry and mealy. This variety crops well, all tubers being about the same size. The haulm is tall and upright, and when well grown each row stands up like a well trimmed privet hedge, which gives this variety its marked characteristic appearance. South Esk produces an abundance of small white flowers. It is immune from wart disease and fairly resistant to blight.

I have mentioned and described those two only, but there are more varieties of recent introduction which will in time take the place of the older kinds when they become better known.—GEO. STUART.

Leaf Soil: Its Use in the Garden.

ALL gardeners like to possess a good heap of leaf-soil. Leaf-mould is made or formed of the leaves of trees which fall naturally and are kept moist. There is no better leaf-soil than that formed naturally in our woods. The reason is because the moisture to which the leaves are subjected is never excessive; they may, at times, become dry, but eventually they decay and become available for use in the garden. If leaves are constantly saturated with water they retain their freshness for a long time. We find such leaves under water in ditches near woods. So, to cause a natural decay, the leaves should be gathered as they fall and placed in flat heaps—not high, conical-shaped ones—in some convenient place. In any great quantity they engender heat and sometimes burn, but if the heap is turned over every four or five weeks such excessive heat will be arrested and a natural rotting take place. Shake out the leaves loosely and sprinkle water on them if dry; do not tread down the heap, let it settle gradually. The turning should be continued throughout the summer and more water used. In the course of eighteen months the mass will be flaky and fit for use. Untouched heaps do not rot before the end of two or three years. If fresh leaves are gathered and treated in separate heaps annually, leaf-soil will be available always.

Sticks and foreign matter should be picked out. Lime and ammoniacal liquor will bring about decay in a shorter time, but the mould may not be as good for plants as that rotted in a natural way. For nearly all hard-wooded plants and trees, leaf-soil is useful and highly beneficial. For promoting the growth of seedlings it is not surpassed by any other ingredient or mixture. Cucumbers will thrive in it; primulas, cinerarias and nearly all kinds of bulbs root freely in it. The proportion for leaf-soil loving plants grown in pots should be one-third. For general use, 1 part to 4 parts of loam and other ingredients. For seedlings it should be reduced to a powder, almost; for primulas and similar kinds of plants, it should be passed through a ¼in. mesh sieve. For cucumbers and other plants in beds, use the leaf-soil in a flaky condition, but always free from bits of wood.—HANTS.

Soil Pests in Winter.

DURING the winter, most pests which infest the soil hibernate or remain dormant, to issue with unabated destructive energy again with the mild weather which announces springtime. They never travel far from their spring, summer and autumn haunts; this fact should always be recognised, for it is possible to take active and drastic measures very often when the land lies vacant. Some penetrate into the ground like the carrot fly, the cabbage root fly and others, to lie inactive a few inches under the surface. Others, again, hie to warmer quarters, obtaining the slightly higher temperature and uniform moistness from rubbish and decaying vegetable matter, all too plentiful in some gardens. Yet again, one may find

Digitized by Google

ite a number under piles of waste like a sticks, old stones, slates and so on. A v remain very close to the surface, particu- ly close to the roots of weeds or edging d other plants; or they may take to the vn and live temporarily in the turf. Still other few hide in dirty hedge bottoms d in clumps of foliage. By trenching a st-ridden spot, soil pests of various kinds e buried and stifled; if ordinary digging is rried out they are exposed for a time and ay fall a prey to fowls or birds. When the soil is loosened, too, the action of soil fumigants is more thorough, and so the use of any soil fumigant, like lime-naphthaline, cresol, household ammonia or formalin, is more than justified. Rubbish must never disfigure any tidy garden, nor will it accumulate where pests are feared. If it is soft decaying matter, then it must be dusted with soot, lime, soil fumigant or other insecticide; or it can be well wetted with some of those liquids I have already mentioned. Hedge bottoms must be cleaned out and the rubbish burnt; clumps of herbage may be dusted with soot or lime, and edging plants may be treated likewise. Just as summer routine demands constant warfare against pests of all kinds, so must the campaign be continued throughout the winter, even when pests do no damage; it is no use "hiding our head in the sand" as the ostrich was said to do at the approach of danger, for potential dangers from pests demand attention just as actual damage in summer must be seen to at once.—CLYDESDALE.

WHAT OUR READERS SAY

A READER'S GARDEN.

IR,—The enclosed photographs of my rden may be of interest to your readers.

The situation is wind-swept and Cupressus acrocarpa has proved itself invaluable as a uick-growing shelter. We have one shelter edge of the cypress in its third year after lanting which shows extraordinary growth.

AN ATTRACTIVE FLOWER BORDER IN A READER'S GARDEN.

THE DECORATIVE VALUE OF ANNUALS IS SEEN IN THIS BORDER.

It is rather too rapid in growth to be really satisfactory as a clipped hedge, but its vivid green makes a pleasing background for brilliant coloured flowers.

The border in the foreground shows the use of annuals in a large rose border.—M. G. HARFIELD (Mrs.), *Hythe, Hampshire.*

FERNS IN THE ROCK GARDEN.

SIR,—I was interested in Mr. Johnson's article on native ferns, for I find them undeservedly neglected. May I supplement his notes with a few of my own.

He confines himself to dwarf ferns, but many rock gardens would have room for our most beautiful species, the Lady fern, for Osmunda regalis in a damp place, and for the polystichums which brave the winter.

Asplenium viride is a pretty little chink-loving fern, like its commoner cousin, A. trichomanes, but with a green stalk. We used to find it and the holly fern in Perthshire; a plant of the latter has been here for about thirty years, but has never increased in size, and I had two from the Pyrenees about three years ago, one of which is already larger than the Scottish one. The best I know is an Irishman growing in Norfolk.

I find the parsley fern and ceterach rather difficult to establish here, the only plant of the latter growing in a brick wall in full sun, not a cool place, as prescribed by Mr. Johnson. I have seen 2oyds. of it in a wall in Co. Galway. I can also recommend Asplenium septemtrionale and A. lanceolatum. With me they like shady chinks, and, indeed, the beauty of these little ferns is that they love what the rock plants hate—damp and shade.

If you have a part of the garden devoted to ferns, it is well to plant primroses and snowdrops among them to flower before the ferns come up, and later on the Himalayan primulas, helodoxa, Bulleyana, etc., will give a welcome variety.—C. G. FIELD-MARSHAM, *Tunbridge Wells.*

AN ATTRACTIVE CLIMBER.

SIR,—Eccremocarpus scaber is always admired, but some would-be possessors of it remain without the plant because of a reputed difficulty in its growing. There is, however, no trouble to grow and keep our subject provided it is planted in light soil which is well drained. These conditions are not so essential during the best months of the year, but they are vital to the life of this climber during the winter months. It is continued dampness round the base of the stem and rootstock that kills. In the more porous and warm soils self-sown seedlings will occasionally appear, thus strengthening their hold in any given place. I have found it so here. Where the plants are not so free of habit, layering can be resorted to, also seed sowing under prepared conditions. Just now, the third week in November, several growths of the plants here are quite green and, in a measure, still active. Other growths are brown in leaf and stem with small bunches of seed pods hanging from them—hence the name "Eccremocarpus"—pendent fruit. Calampelis is another name this plant is known by.—C. T., *Ampthill.*

POTATO DUKE OF YORK.

SIR,—You will probably remember that much correspondence arose out of my mentioning Duke of York and Midlothian Early in an article on potatoes in a spring number of THE GARDEN, and opinion was divided as to whether these varieties were synonymous or not. I discussed the subject with Mr. J. R. Poad and with Mr. Cuthbertson and both declare that there is no difference between stocks of these now retailed under the different names. On the other hand, all my farmer friends who have cultivated the two varieties for a great many years, are emphatic that there is a difference between the *original* Duke of York and the variety that is now sold as Midlothian Early, but the difficulty is finding anyone who has any seed of the so-called original stock. I was hoping to be able to come across an old grower in this district who has propagated his stock for, say, fifteen or more years (one grower has done this with Ninetyfold, but not with Duke of York), but I have not been able to do so yet. If so, we may be able to see if there really is any difference. However, my farmer friends assure me that Duke of York as they knew it years ago was a deeper yellow in the flesh than Midlothian, closer in texture (*i.e.*, sadder), when cooked, earlier, but not such a good cropper. The habit was also said to be different, being dwarfer. I did not enter into the recent discussion because it was difficult to prove the case, one way or the other, and the arguments took up too much of your valuable space. I merely give you these facts to show that there is still a difference of opinion.—NORMAN LAMBERT.

SYNONYMS AMONG TULIP NAMES.

SIR,—In perusing several bulb catalogues at leisure one cannot but be struck with the great number of named varieties each represented as the best of its class or colour. Now,

Digitized by Google

if two flowers, otherwise identical, in every respect, bloom at definitely earlier or later dates, or if they have shorter or longer stems or other definite differences, there is excuse for various names — not otherwise. A short stemmed variety may be entitled to be described as "best" in a wind-swept garden, while in a more favoured position her longer stemmed sister may reign supreme. Occasionally one encounters a very subtle difference. Can anybody tell me the difference between the old true Yellow Florist tulip and Bouton d'Or, beyond the fact that they are the product of different parents and the latter increases out of all proportion to the former? Since acquiring the famous collection of tulips lately owned by the late Rev. Joseph Jacob, my list of varieties has jumped by several hundreds and as some of my stocks are growing into scores of thousands, I make no excuse for pleading the desirability of fixing standard names for standard varieties. Frequently one is momentarily "caught out" by an enquiry for a known variety under an unfamiliar name. Thus we find the well known May-flowering Tulip Bronze Queen is known as Clio, Biscuit; Sensation, Duc d'Orleans. That magnificent Tulip Prince of Orange is also to be found as Orange Beauty, General Ney and Gesneriana aurantica major. Then we have Boadicea, which is really larger, brighter and longer in the stem than Hammer Hales, which is in five cases out of six supplied when Boadicea is called for, and I see now in a Dutch catalogue that they are actually offered as the same thing. Panorama, Monument and Fairy are identical, though anything less fairy-like than its rich glowing chestnut would be hard to find. Cramoisie Brilliant, Carmine Brilliant and Sparkler are identical. Bartigon = Early Darwin (Barr only) = Lord Duncan (Hogg and Robertson). Mrs. W. D. Fish = Fashion = Mrs. Potter Palmer. Nauticus = Sir Edward Grey. Dream = Grand Maître = Rêve de Jeunesse. Joseph Israels = The Sultan = Suzon. Ravenswing = Faust. Wm. Copland = Sweet Lavender. Blushing Bride = Isabella = Shandon Balls. Picotee = Maiden's Blush = La Vierge. And so the list might be extended *ad infinitum*. Is this another instance of the tulip's peculiarity of "breaking" after it has left the raiser's hands? A rose by any other name would smell as sweet, but can a tulip add in this manner to its attractions?—HERBERT G. LONGFORD.

HARDY CYCLAMEN.

SIR,—Some very pretty and even striking effects may be obtained by planting freely of these lovely little plants, for sheer hardiness they are difficult to beat, as witness C. Coum, the flowers of this species appearing in quantity during February and March, and on occasion I have gathered many blooms on Christmas Day; in grass beneath an old tree or colonised in the cooler parts of the rock garden, C. Coum, with its deep red flowers and round deep green leaves, purple beneath, is one of the prettiest and most satisfying of spring flowers.

C. ibericum, another spring-flowering species, is characterised by bright red flowers, each having, at their base, a purple spot; the leaves are faintly undulated at the edge and distinctly zoned with white. Flowering in February and March, it is closely followed (March to May) by C. repandum, rosy red flowers with purple base and white zoned leaves, and before leaving the spring-flowering forms, mention must be made of that fine garden form of ibericum named Atkinsii, and of the albino forms of Coum and ibericum. These harbingers of spring are noteworthy for extreme hardiness, Coum especially being resistant to the severest weather and appearing to gleam ever brighter as the gloom of mid-winter descends upon it. Of the late summer and autumn-flowering types, C. neapolitanum has white or red flowers with, in either case, purple basal colouring; the flowers appear before the leaves, but the latter are usually developed before flowering has finished, whereas in the spring-flowering section, the leaves are contemporary with the flowers. The leaves of neapolitanum are large and furnished with irregular "teeth," but are not so lovely as those of C. africanum, sometimes known as hederæfolium, for, beautifully mottled and marbled with white, they render this plant beautiful of foliage as of flower, the latter in pink and red shades and there is also a white form.

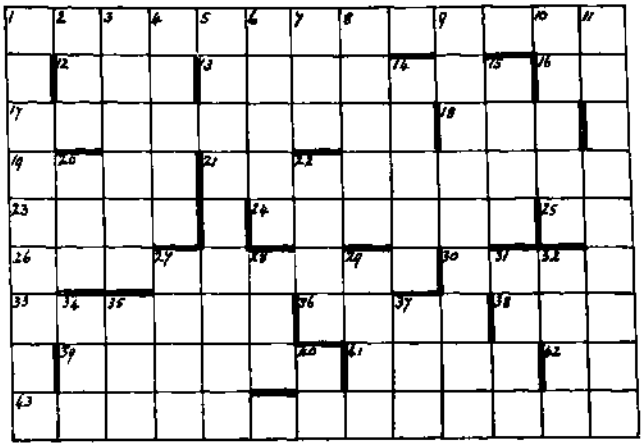
C. europæum has bright red and slightly fragrant flowers and contemporary leaves, these mottled with white and tinted purple beneath; these summer-flowering forms bloom from August to October and as with the spring species, are ideal for massing in half-shaded situations in border, thin woodland, grassland or rock garden. They resent disturbance and should be allowed to carpet the soil with self-sown seedlings, and in a comparatively short time will form masses of flower and foliage, a lovely feature of any garden, large or small.

An annual surface dressing of leaf-mould is greatly enjoyed and proves of great benefit but otherwise cyclamen are not fastidious, thriving in any cool and ordinarily good soil and perhaps never looking or doing better than when growing in thin woodland, the red flowers of Coum, for instance, being extra pretty when visualised between brown hazel stems; excellent effects are also obtainable by planting cyclamen as a groundwork to American plants, and so used, they thrive luxuriantly.

As a matter of interest, it may be stated that these plants attain to a great age and will form corms of huge size. I have seen corms of the dimensions of a good sized plate and as hard as a piece of oak, yet those ancients lose nothing of vitality but simply ask for immunity from disturbance. In conclusion, I may advise planting cyclamen when in a dormant condition.—RALPH E. ARNOLD, *Campden, Glos.*

A HORTICULTURAL CROSSWORD.

Many of our readers may be interested to try the accompanying horticultural crossword puzzle for their own amusement sent in by a correspondent. The result will be published in our next week's issue. No prizes will be given and no solutions must be sent to this office.



ACROSS.

1 B. corallina (evergreen flowering climber).
12 Plant which is an emblem of bitterness and grief; herb of grace.
13 Enchanter.
16 First two letters of shrub symbolising honour.
17 L—— californica, hardy annual (Compositæ).
18 Transport for plants.
19 Lily associated with idleness.
21 Good digestion (may your gardening give it you).
23 Indigo plant.
24 Mixed grain, especially rye and wheat.
25 Repeat from the beginning (abb.)
26 Particularly choice (Fr.).
30 South American species of holly.
33 Thorn apple.
36 Pupil of Linnæus who gave his name to a genus of evergreen flowering shrubs of which the American laurel is one.
38 One-celled fruit with a hardened pericarp.
39 Chastising (schoolboy word).
41 Hindu cultivator.
42 First half of another word for lawn.
43 Botanical name for the native elecampane (two words).

DOWN.

1 Campanula —— Miranda.
2 Series of years.
3 Style for arches and summer-houses.
4 Nut chewed by Malays.
5 Cotyledon used for edging.
6 Botanical name of a plant whose stalks we eat.
7 Scotsman's name.
8 What the soil does when it lacks 15 down.
9 American date plum.
10 Epic poem (Gr.).
11 A thicket of willows.
14 Acer.
15 Beneficial to gardens.
20 Number.
22 What the nurseryman must do carefully if his plants are to arrive undamaged.
27 Husk.
28 First syllable of buttercup order.
29 The skin of flax.
31 First four letters of the other name for snapdragon.
32 New Zealand shrub; twice 42 across.
34 Husk; beard of corn or grass.
35 Toad-fish.
37 Solution of potash and soda in water.
40 First half of —— Mrs. Bradshaw.

STERNBERGIA.

SIR,—Our experience here with sternbergia may be of some use to north country gardeners reading Mr. Cahen's note on page 698. Having admired the autumnal display of S. lutea both on the Continent and in the southerly English counties, I have repeatedly planted bulbs here, always with the same depressing result. Even when given a full south aspect at the foot of a wall they have never produced any flower, which leads me to conclude that they require more baking than they can derive from our Scottish sunshine. Conditions may be more favourable on the east coast, but I have never happened to see this attractive plant flowering in Scotland. It would be interesting to hear whether it ever does so.—HERBERT MAXWELL, *Monreith.*

HIRSUTE CHRYSANTHEMUMS.

SIR,—In the issue of THE GARDEN of November 13th, in Flower Garden Notes, mention is made of hirsute chrysanthemums. About thirty years ago I used to grow them with great pleasure, and would gladly do so again if I could procure them. If any of your readers could put me in touch with anyone from whom I could procure cuttings I would greatly appreciate it.—H. MACBETH-RAESIDE, *Newbury, Berks.*

DECEMBER IN THE GREENHOUSE

Winter-Flowering Begonias.

AS the flower buds open, a comparatively dry atmosphere, with a slight lowering of the temperature, about 55 degrees at night, will help the flowers to maintain their freshness for a longer period.

To keep in check the spread of thrip and rust—the pests most to be feared on begonias—and to forestall the necessity of doing it when the plants are in full flower, vaporise the house on two successive evenings. For this purpose use a nicotine preparation at a strength 100 per cent. more than would be used to kill green fly. And for a similar reason, go over the plants carefully and touch any mealy bug with a drop of methylated spirits from a pointed stick or small brush.

Also give the shoots a final readjustment to their stakes, of which there should be enough to support the plant in a natural way without their being offensive to the eye.

When the flowering period is over the plants "rest," normally from January to March. Although producing stems annually these begonias, with an exception, do not form a tuberous root as we understand the term, but have a root stock in the form of a cluster of fleshy buds. Under these circumstances they do not survive the "drying off" system practised on the true tuberous begonia. Yet they must be rested and this is brought about by reducing the water supply to the lowest minimum compatible with retaining the plumpness of these underground buds. A further concession to induce this "resting" and to economise room is to cut away the spent flowers with a fair part of the growth. Another notable point about this section of begonias is that they resent being rested in a cool house, but must have warmth with plenty of light.

The exception quoted when referring to the formation of tuberous roots is found in two to four year old plants, which might be called "clibran" winter-flowering begonias for distinction.

Plants of this age form bulbs which may be "rested" and restarted into growth after the manner of the ordinary tuberous begonia.

First year plants of this type require rather more care in resting, indeed, it is, I think, the most crucial period in their whole cultivation.

The situation must be neither cold nor hot, and water given in just sufficient quantities to retain the stem and leaves as long as possible.

If too much be given, decay of the root stock may set in, and too little causes the foliage to fall away too early and there is a difficulty in the plants resuming growth when required.—WM. MCCARRELL.

Soot Water for Pot Plants in Winter.

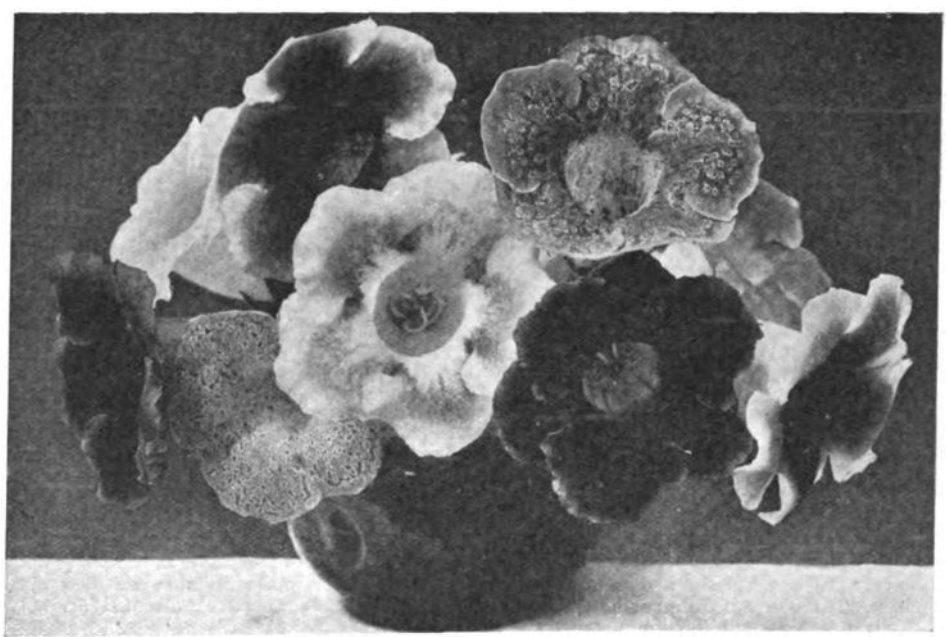
THE application of stimulants for plants in pots which are located in a greenhouse during the winter is not always appreciated, and it not infrequently happens that those valued for the beauty of foliage are not seen at their best at this time of the year. There are, as we know, several proprietary articles which are of great benefit in keeping plants in vigour and in imparting a brilliancy to the leaves, without which they lose much of their charm. Not only foliage plants but those which flower in winter are benefited by stimulants, and in this connection one has but to mention primulas, cinerarias, azaleas, and genistas like Cytisus fragrans. One of the commonest stimulants, within the reach of all, is soot which has stood some time in the open and been turned over a few times to rid it of "fire." This, if put in a coarse bag and placed in the water tank, will be found a safe and sure remedy for stimulating most plants, and after a few applications the change in foliage is most marked, as it assumes a dark green that is an indication of a vigorous forward movement having taken place.

It is important to note that soot should never be used when in a new state, and is best after it has stood some time at least in the open air. In applying it in a liquid form, it is always best to do so after the usual watering, and no attempt ought to be made to give plants this or, indeed, any stimulant when they are dry. We are sometimes apt to fall back on highly concentrated manures when considering a "pick-me-up" for our plants, and overlook this homely remedy, which, rightly given, seldom, if ever fails. —W. F.

Start Some Gloxinias Now.

GLOXINIAS are so attractive and so useful for decoration that every effort to prolong their "season" is justified; for that reason we advocate a start being made with some of the tubers this month, others to follow at intervals and a succession of bloom ensured later in the year. Old corms may now be shaken out of their pots, in which they have been resting in quite dry compost for a time; nice firm ones are best for our purpose at this time. Such corms are placed in a box of compost consisting of half soil and half well rotted leaves; they can be placed there, an inch apart, and just covered with the compost; after watering, the box is placed quite close to the pipes so that a good bottom heat may send them fairly quickly into growth. Care must be taken to see that the compost never gets dry; light sprayings overhead encourage growth, but these do not keep the compost wet and a fairly good watering must be given now and again. When top growth becomes well established, the corms are lifted carefully with as much compost about them as possible and as little disturbance as need be, and then put into 4in. pots. In due course they will require a shift, into 5in. pots probably, the compost still being much the same except that a little sand and some cow manure may be added; town growers who cannot get cow manure may use hops, but composts containing such semi-artificial mixtures are best made up a few weeks in advance. In repotting, take a small pot, the same size as that containing the plant, place this in the larger size and then pack soil tightly round it. Remove the pot, knock out the gloxinia and slip it, with ball of soil, intact into the hole; very little work is needed in this way and there is no danger to the brittle leaves; water carefully, but fully afterwards. Do not spray growing gloxinias overhead, but let the air be moist for them.—H. A.

[The illustration of gloxinias which appears on this page is by kind permission of Messrs. Sutton and Sons.—ED.]



AN ATTRACTIVE BOWL OF EXOTIC-LOOKING GLOXINIA BLOOMS.

The Damping Off of Plants, Leaves and Flowers.

IN late autumn and throughout the winter months amateurs suffer much loss through the damping off of leaves, stems or whole plants. As long as we have sunshine and drying winds there is not much difficulty experienced in keeping the atmosphere inside the glass-house buoyant; but immediately the damp, sunless days come, with fogs frequently, plants suffer unless they are very carefully attended to. Take, for instance, pots of lobelia or tufts of these plants in boxes. When fogs come the centres soon become a mass of mould and the whole plant is lost, if the specimens have been carelessly watered and the moisture has lodged in the centre of the massed leaves. All kinds of plants of a similar character suffer in the same way. If convenient, the plants should be kept on shelves so that air can reach them all round, and water applied only in the early part of the day when bright weather prevails—indeed, all choice plants should be watered early in the day and in fine weather, pouring the water on the soil and not on the leaves nor on the stems of soft-wooded plants such as winter-flowering begonias, primulas, cinerarias and calceolarias. Perhaps there is more loss among the zonal pelargoniums than any other class of plant, mainly for two reasons, their soft, woolly nature and sappiness. The pelargonium is a plant that will live a long time without water in the winter season but, unfortunately, cultivators do not realise this enough and apply water in winter almost as freely as in the summer. Another fruitful

Digitized by Google

cause of loss of plants is found in the use of saucers to contain water. Only in very exceptional cases should saucers ever be used, and even then drained water should be emptied away. In the winter, water in saucers is bound to cause the soil to become sour and eventually kill the roots. The water used should be of the same temperature as that of the house, as applications of very cold water tend to the damping of leaves and rotting of roots and stems. Surface moistening of the soil is also bad for the plants; this is frequently done, whereas a thorough soaking of the soil only when the latter is really getting dry will do a lot of good and not tend to loss of plants through damping. Recently rooted cuttings possess a few roots only; they should be grown in a small bulk of soil—in small pots or in shallow boxes, and more care should be bestowed on them than on established plants. Daily attention to the plants is essential. Decaying leaves and flower petals should be removed regularly, as one bad petal will soon cause a whole truss of flowers to decay; especially is this the case with zonal pelargoniums. Overcrowding is bad for the plants always; all watering necessary should be done in the morning and spilled water dried up. As much ventilation as possible should be given early in the day and very little after midday. Front ventilation on hot days will help to dry up the moist atmosphere, but the main ventilation should be at the top of the house. A gentle heat in the pipes and judicious ventilation will combine to preserve the plants from damp generally.

Plants for the Greenhouse this Winter.

NEVER before has it been more difficult to know what is best to do with greenhouses that, in early autumn, were stocked with a variety of plants which need a certain amount of heat to tide them over winter. The restrictions on supplies of house fuel, and its abnormal cost, has had the effect of many greenhouses having to be closed down, so far as applying heat is concerned, and the plants already in them are having "to take their chance." The problem which confronts quite a number of folk is how to fill the vacancies which will be caused, and what is the most economical course to pursue to furnish the greenhouse with plants, so that it may be gay by another summer. I think most of us have given precedence in our houses to plants of a permanent character—pelargoniums, heliotropes, vallotas as examples—and have not always remembered that it is quite possible to begin the "gardening year" in March under glass and have a good show by June by using annuals. It is quite true that, among amateurs, there are not a few who, while recognising the worth of annuals in the garden, fail to appreciate them as pot plants. Necessity will, I imagine, bring to the front many annuals that may be grown to perfection under glass without any artificial heat whatever and make a place quite attractive. A consideration of some of those suitable for bringing this about is here suggested. They can be raised from seed sown, say, at the end of March, in pans of light soil, given a shift into another pan, or small pot for preference, and finally potted off into 5in. or 6in. pots.

What May be Grown.

Clarkias, thunbergias (for trailing), mignonette, Rhodanthe maculata and R. m. alba (a dozen plants in a pot), cosmeas, balsams, Phlox Drummondii, salpiglossis, godetias (particularly the double forms), sweet peas, lavatera, sweet sultans, jacobæas, nasturtiums (dwarf) and Chrysanthemum tricolor.

These are but a few of the annuals which are of service for potting. The cost of such a display will be found trifling as compared with buying a fresh stock of the orthodox plants seen in so many houses, and the result cannot fail to please when they are grown as individual plants and not in masses.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Owing to the number of hints which are sent in, we desire that, in future, each hint should be sent in on a post card, and should be limited to 150 words. Payment for these hints is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF-GUINEA HINT.

How to Prevent Fumes and Smoke from Oil Stoves in Greenhouses.

Many people have found it necessary to use an oil stove to keep frost from the greenhouse. To prevent the stove smoking the wicks must be kept trimmed and the burners clean. If a block of camphor be dissolved in each quart of paraffin the light will be brighter and the fumes not so strong. Also the lamp will not smoke. Another tip is to soak the wick in vinegar and then dry it before using. —T. H. H.

Killing Tree Stumps.

I am often asked how I killed the stumps of two large elm trees which four years ago were cut down near the high road in my garden. The roots came sprouting up all over the place and were a great nuisance. After the tree was cut down and cleared away, I dug a good deal of the soil away close round the stump and peeled off all the bark, leaving it quite bare. As the sap runs up the bark of a tree, it was a most efficient way of killing it. Since that date no sprouting roots have been seen. If in digging the garden, tree roots are dug up, they are always dead and rotten. The remaining tree stump makes a good garden seat.—M. E. T.

A Use for an Old Garden Broom.

When the garden broom is wearing down, do not throw it away. Take it to pieces. The handle makes a good strong stake and the rest is most useful for propping up plants of rather straggling habit and for keeping birds from pecking out the buds from primroses, etc.—L. B.

How to Preserve Delphiniums, Scabiosa caucasia and Pyrethrums from Seeds.

These charming herbaceous plants are easily grown, but during the dormant season slugs will travel miles to devour the young growths just below the surface. I have found the following method quite a success. Secure a basket of air *slaked* lime, and place a good handful over the crown of each plant, a mere sprinkling is useless. There is no need to be afraid, the top of the plant will be covered with lime, in fact large roots may require two handfuls. In the spring, clean, fresh, healthy young growths, especially the delphiniums, will push up through the lime and flower freely. Remember, the lime must be air slaked, not fresh lime in lumps. Thousands of the above plants are destroyed annually by slugs. Here's a remedy, now go ahead.—T. B.

Successful Holly Growing for Its Berries.

Hollies grow best in chalky soil and when well established furnish heavy crops of berries every year. When planting holly bushes in deep, loamy soil, cut large square holes, 4ft. wide, 3ft. deep, clear half of the loam away, then add chalk, mixing chalk and loam together in equal proportions, then plant firmly. Be sure the holes are hard and solid at the bottom. Large holly bushes, with no berries year after year, require root-pruning; cut a ring round the bush 4ft. from the trunk and 3ft. 6ins. deep and cut all tap roots, then fill up with chalk or mortar rubble.—B. R.

A Good Way to Sow Annuals.

Some annuals cannot satisfactorily be transplanted and the following method of sowing will be found helpful. After the bed has been prepared, take some sand and lay a handful of it on the ground at stated intervals, according to the size of the annual. For instance, for a plant of high growth like Lavatera Loveliness, the patches of sand should be quite a yard apart. When the ground is fully marked out with white patches, dibble four or five seeds into each patch, one line after another. This method is infinitely more economical of seed than the usual way of sowing in drills or broadcasting, and has the additional advantage that, if the seed is slow in germinating, the ground can be hoed between the patches, which can easily be seen.—R. H.

A Serviceable Hoe.

I used to find when using a hoe in the flower border, that occasionally some young plant or more often a sprouting bulb was sadly mutilated or even cut off by the sharp blade. I have now dispensed with the ordinary Dutch hoe to a certain extent, and have made a very serviceable tool, which has all the advantages of the hoe and none of its disadvantages, by taking the handle off an ordinary gardening trowel and fixing the spike of the trowel into a long handle. The spoon shape of the blade enables me to get between all the closest growing plants and bulbs without much fear of an accident, using it in the same manner as the Dutch hoe.—B. S. H.

A Simple Method of Catching Cockroaches.

These insects sometimes do very considerable damage in glasshouses by eating off the tender growing points of various plants. A good method of trapping them is to procure some clean jam jars of the 1lb. size (the number required will depend upon the size of the house), and into the bottom of each pour about 1in. of sweet oil. Place these overnight in suitable positions in the house and lean two or three pieces of wood against them for the insects to crawl up. Examine the following morning and remove the dead bodies from the oil. The same oil may then be used the following night. After this has been continued for four or five successive nights it will be found that the number of cockroaches caught will begin to decrease. A period of a fortnight may then be allowed to elapse before the traps are set again. This is a surprisingly effective method, and if persisted in an infested house will soon quickly cleared of these undesirable creatures. Needless to say it proves equally as efficacious in dwelling houses or outbuildings where these pests abound.—T. H. E.

MISCELLANEOUS NOTES

Wistarias—Their Pruning and Culture.

WISTARIAS are often disappointingly flowerless. This defect is frequently attributed to anything but the real cause. Trees which grow well in the North and Midlands and yet yield few blooms, or those planted with a wrong aspect, which equally (like the Biblical fig tree) produce nothing but leaves, can be made to bloom abundantly if they are properly pruned. All gardeners know that, but even in the counties south of the Thames, where wistarias grow rampantly and are usually most floriferous, it is by no means rare to come across trees which flower meagrely for want of pruning. Owners of such should, without delay, subject them to the following treatment. The main and side branches should be trained to cover all the available space, every one of them being allowed sufficient room in which to develop, with a view to its leaves and flowers covering its support between it and the next branch.

When this has been done it will be found that in old established trees there are many straggling and badly placed branches, and weakly shoots, for which there is no room—as there must be no crossing of the branches. These useless growths should all be spurred in the winter while the sap is dormant. Spurring consists of shortening each growth to within two buds of its base.

As in the case of apple and pear trees, flowering spurs will result from such pruning.

Although in an ideal situation the wistaria, when properly nourished, will produce flower spurs without any pruning being done (like plum and cherry trees), yet, after a lapse of years, fewer and fewer flowers are produced unless the young growths are cut back to two buds. This is necessary, not only to produce flowers, but also to admit light and air, and to prevent overcrowding of the branches, which always results in weak growth. Sometimes the oldest branches of a wistaria become worn out and are naked save at their apices. In that case a young strong growth should be trained to take the place of the old one, which should be cut right out. When the new branch reaches its space limit it should be shortened to a bud. Its laterals, like those of all the other branches, should be spurred during the winter.

A lack of phosphates in the soil is another cause for flowerless wistarias. An easy and most efficacious way of supplying this lack is to dig in one or two largish bones into the soil around the roots of the trees. These bones will give the trees all the phosphates they require for years, as bones disintegrate slowly and the plants can obtain food from them as their needs demand it. This continual provision of phosphatic nourishment will not only help wistaria to produce flowers, but will deepen their colour and increase their size. Bones, either entire or broken, are capital things to give to *any* flowering tree or shrub that is chary of blossoming.—VICTORIA SLADE.

Stems Needing Protection.

THE uncertainty of the weather in this country often makes plants unable to withstand spells of severe frost. Quite commonly part of the winter may be mild and wet so that many subjects are kept in a semi-active state. Their stems, being in a succulent condition, suffer much more from extreme cold than if the greater part of the sap had withdrawn to the roots. The delicate tea roses, evergreen magnolias, tree peonies and bays are instances which come to mind, but there are many others. In some cases not a great deal can be done to protect the plant as a whole, and if the conditions are very bitter much of the smaller growth will have to be sacrificed. There is no reason why the damage should be allowed to extend to the plant as a whole if a suitable method of stem protection is adopted. If one can keep the stem alive and healthy, most of these somewhat tender subjects will grow with great vigour when the spring comes and more than make up any loss which they may have sustained. Stem protection may not be needed in every winter, but it is just as well to be prepared to adopt this measure at the first sign of really sharp weather setting in.

Probably the best way of protecting the stem of a plant is to bind it closely with hay bands. If the hay band is well twisted it will to a large extent resist the penetration of moisture. If, as sometimes happens, there is a thaw, succeeded by a second frosty spell, it is well to examine the hay, as when this is sodden it should be replaced by dry material. Material that is thoroughly wet does more harm than good in frosty weather. Not only should the stems be heavily bandaged in the way described, but it is, as well, a good plan to litter the ground with a thickish layer of bracken, straw or hay. The roots of many plants grow perilously near the surface of the soil and if this should be frozen hard to the depth of several inches serious damage is sure to result.

Home-Gathered Seeds.

AS a general rule there is not very much advantage in the owner of a small garden—or, in fact, a large garden—in saving one's own seeds, thinking thereby to economise. We all, I imagine, desire the most prolific display of flowers for the longest period, and the best crops of vegetables, and we do not like to sacrifice either for the purpose of obtaining seeds by restraining their output at mid-season. There are exceptions, of course, but to make a practice of looking to the garden for supplying seeds which may be sown and produce satisfactory results, equal to those purchased through a reputable seedsman, is altogether a mistaken idea. When it is remembered that, mostly, "home saved" seeds are those harvested at the back-end of the season, when plants are spent and are at their lowest vitality, it is not to be wondered at that there comes a time when the amateur seedsman is not altogether satisfied at the labour expended. Runner beans may prove good for several years, but even with them it is not wise to rely too much on home produce. I have known men who have boasted that "they always save their kidney bean seed," but the truth is that one could scarcely discern the original variety in the plants produced from the seed gathered so long. It is not difficult to explain how degeneration is brought about, not only in gathering seed in autumn when plants have cropped well and have become weakened in consequence, but by bees and other pollen distributors which spoil the strains of seeds that, in the first instance, were pure. It is, as is known, sometimes desirable to obtain seed harvested and grown in different localities, and it is to the seedsman to whom we must look for supplying the best. Growing for seed is a business understood by those who embark in it, and select seeds from plants full of vitality, carefully eliminating "rogues" and choosing only those that are known to be pure. When sweet peas rose so rapidly in public favour years ago, one heard sometimes of people saving their own seeds, but I never met with anyone yet prepared to let the first and best sprays go to seed and to sacrifice blooms; yet that is precisely what the professional seedsman does. Our seeds, which we sow in autumn or spring, do not all ripen in England. Many things that beautify our gardens are grown and harvested under better conditions in regard to climate than always obtain here, and it is because of this that it pays the best to secure seed from those who lay themselves out to supply.

An instance came under my notice of a man who made a practice of saving seeds from sweet peas for several years. On the last occasion he did so, he failed to gather it before the end of September, when flowers had long ceased and when the plants were at their lowest ebb. The following year he was rewarded by puny plants, lacking stamina, among which were vetches, a demonstration of reversion to type and degeneration. It was a lesson I never forgot!—CLAREMONT.

Lime—Its Use in a Garden.

LIME is of great value in a garden. Some cultivators do not realise that, in addition to rapidly breaking down the texture of organised matters, it is a manure as well, some of its salts enter the structure of all vegetables. It purifies the soil, too. When a garden has been manured year after year and lime applied, the soil has, no doubt, become sour, to the detriment of plant life. In such cases the proper thing to do is to apply lime as fresh as possible from the kiln. Frequently, one reads of cases where the lime has been left on the surface of the soil all through the winter. Only in exceptional cases should lime be so exposed as it absorbs carbonic acid from the air, which converts it into chalk. With a few exceptions plants need lime; stone fruits cannot be grown satisfactorily without lime being present in the soil. I would say, at once, all readers who have a heavy loam or clayey soil to deal with, should use lime freely, especially in the autumn time, applying and lightly covering it with soil, always mix it with the top 9ins. of soil. Heavy or clayey soils contain rich plant foods and lime, judiciously applied to them, liberates those foods and, in simple words, feeds the plants with them. How it helps to crumble stiff loams and renders them easier and pleasanter to work. A good average dressing of lime would be six to ten ounces per square yard.

One hears cultivators say of lime, "it sweetens the soil." This is very true; it is also true that the presence of lime in the ground lessens the risk of loss of plants from fungoid growths. The latter cannot live and spread in a soil well impregnated with lime. Tender seedlings may not thrive in a soil in which there is fresh lime, but the majority will if there is some old mortar rubble added to the compost. Thus, in some form or other we must apply lime. One dressing every three years will be sufficient, generally. When soil is not cropped—from November to February—lime should be applied; its application should precede applications of organic manures and fertilisers, generally. I think it best to do without any dressing of organic manures when lime is used that particular season, in cases where it is known that the soil is heavily charged with humus. But where we have to deal with a poor, hungry soil, manure freely now—in the autumn—and add the lime in February. Do not use lime at the same time that artificial manures are being applied and never use lime and soot together.—G. G.

A GOOD RESOLUTION FOR THE NEW YEAR!

OUR SERVICE BUREAU

Though so many subjects are dealt with in each issue of THE GARDEN, *it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, there is always information available from a staff of expert contributors and consultants; and there is no charge for this. It is one of the additional means of service which* THE GARDEN *is glad to render to its readers.*

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope and the coupon, that will always be found in each issue, shall be sent with the enquiry. We would point out, however, that we cannot undertake to supply readers with plans and designs of gardens, but will willingly assist in giving suggestions for planting.

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2.*

We have selected the following enquiries, with their answers, as being of more general interest, and therefore worthy of publication.

Treatment of Snowy Mespilus.

I am putting in a tree of Amelanchier canadensis (snowy mespilus). What is the best situation for this? My garden is open, sunny; soil sandy loam, where it has been well worked fairly light, some parts rather clayey and heavy.—A. E. B., Wootton Wawen, near Birmingham.

Amelanchier canadensis is not a difficult subject to cultivate. It will thrive in any soil that is not too dry and poor on the one hand, or water-logged on the other, and the situation which you suggest for it we should think would prove quite suitable. It is a most decorative subject both in late spring—about the end of April—when it is a mass of white blossom, which, unfortunately, does not last very long, and also in autumn, when it carries rich autumnal tints.

Loganberry Fruit Spoilt by Grubs.

For some years I have persevered with my loganberries with a view to improving the results, but am still unable to account for the presence each year of a worm in the fruit. The old canes have been cut away annually, and the new growths, which have been treated liberally with manure at the roots, have shown themselves as strong, healthy canes. They have flowered freely and the fruit has appeared, but as the berries mature they are practically all spoilt by the activities of a worm which works right up the middle of the fruit from the base, the berries becoming withered from the base upwards. In some cases the berries have ripened and seem quite healthy, but on picking, the worm is found inside. If you could enlighten me as to a successful form of treatment I should be grateful. I may say I know of gardens in this vicinity where beautiful fruit is gathered and no trace of the worm found, and I am wondering whether it is desirable to try new canes.—J. C. S., Oswestry.

The worm in the loganberries is the grub of the raspberry beetle pest. It is prevalent in many gardens and is not the easiest of pests to get rid of. The beetles live in rubbish and *débris* of one kind and another near the plants, and in spring lay their eggs in the loganberry flowers. From these eggs the grubs hatch and feed on the developing berries, with the results of which you are familiar. Remedial measures are, in the main, directed to the destruction of the breeding grounds of the beetles. Firstly, all old canes must be cut out annually and burned. If wooden poles support the wire trellis, these must be cleared of all loose bark under which the beetles can hide, and ought to be painted with Solignum or some such material. All rubbish of any kind must be kept away from the plants. Then, in late March, fork crude naphthalene into the ground about the canes at the rate of 3 oz. to 4 oz. to the square yard. Beetles may also be trapped when laying their eggs on the blossoms by shaking the canes over a newspaper or umbrella, so that the beetles are dislodged, and may be collected and destroyed. They are small, brown beetles, and by this shaking of the canes it is possible to catch dozens at one visit. If these measures are persevered with over two or three seasons and the ground about the canes is kept constantly hoed in springtime, we think you will find that trouble from these grubs will be very considerably reduced.

Winter Treatment of Pampas Grass and Red Hot Pokers.

Could you please inform me the procedure I should adopt with (1) pampas grass, (2) red hot poker before the winter? As you can see, I am very much an amateur. I have seen pampas grass bound (tied up) over for the winter and red hot pokers look as though possibly they should be.—R. B., Croydon.

It is not necessary to tie up the leaves of these plants during the winter months. Simply clear away all loose leaves—grasses—especially those that are dead in the centre of the pampas grass, and very lightly dig the surface soil and bury a little rotted manure round the base of the red hot poker. In spring cut off the brown ends, if any, of the leaves.

Sweet Peas in an Unheated Greenhouse.

I want to grow some early show sweet peas. I have a large unheated greenhouse, and propose to grow two rows about 3ft. apart up the centre. Should I sow the seeds in 60 pots and put in warm greenhouse at once, and plant out about 8ins. apart when about 6ins. high? Should I take out the tops after planting?—W. N., Christchurch.

As it is now rather late in the season, it would be well to place the seed pots in a warm greenhouse, but as soon as the seedlings are clear of the soil the pots should be gradually removed to an unheated frame where they can be kept close to the light and receive plenty of air on all possible occasions. The seedlings should be stopped when they have made three pairs of leaves. Firm planting and an abundance of fresh air whenever possible are essential to success with sweet peas under glass.

The Failure of Fig Crops.

I shall be glad to have advice about a fig tree now about sixteen years old. Twice every year the tree is covered with figs, which turn yellow and drop off before they are ripe. The tree is planted against the kitchen wall, and probably gets heat from the chimney which runs up behind, and also from some pipes to the greenhouse which are underground. It faces south, but is shaded from the sun after about 2 p.m. by the wall of the house. One year there were about half a dozen very large dark purple figs which ripened. The gardener has tried pruning both branches and roots at various times.—A. F. W., Torquay.

There are several reasons why your fig tree fails to mature a crop. In the first place, the tree can mature only one crop in a season, and that on the shoots made in the previous year. The current year's growths may also produce fruit, but too late to ripen out of doors in our climate. The whole object of the cultivator should be to secure short-jointed, well ripened growth during the summer that will carry a good crop next year. This is attained by correct pruning and cultivating. We note that you have tried pruning at various times. The tree must be pruned every year during summer and winter. In the summer the shoots should be thinned so that each has ample space, the coarse and crowded growths being shortened to five or six leaves, and the short, stocky shoots trained in to the wall. Full exposure to sun is necessary for all and overcrowding is fatal. At the winter pruning, soon after the leaves fall, the growth should be further thinned and branches cut away where they are too thick, leaving only enough to furnish the tree with bearing wood for the next year's crop. When the fruit is set, a mulch of rotted manure should be laid over the roots, and the trees supplied with water during dry spells. It is essential that there be ample lime in the soil, and a winter application of finely broken mortar rubble evenly spread and dug into the top soil will be all to the good. Against the kitchen wall the tree is, perhaps, not in the best of positions, but treated on the above lines it should fruit well each year.

Limestone Plants in Full Sun.

I have a rockery, situation south, in full sun; soil, loam, road grit, leaves and stable manure (well rotted). To accommodate both lime-loving and peat-loving plants I have dressed one-half with old mortar rubble and the other half with peat. A deep depression in the centre I can keep moist during the summer months. I cannot yet obtain a definite classification of lime and peat loving plants from any source. Will you kindly recommend a few plants of both types for the rockery? Quite a few names will serve. Will the kabschia saxifrages flourish in this sunny aspect, or what species of saxifrages would you advise?—G. C. G., Harpenden.

Acantholimon venustum, Achillea ageratifolia, Æthionema grandiflora, Alyssum montanum, Androsace sarmentosa, A. Chumbyi, Arenaria montana, Aster alpinus, Dianthus cæsius, Campanula garganica and C. hirsuta, Erodium chrysanthum, E. cheilanthifolium, Geranium argenteum, Gypsophila repens, Hypericum polyphyllum, Linaria alpina, Erinus alpinus, Onosma echioides, Phlox subulata, Primula auricula, Saxifraga Aizoon, S. Burseriana, S. Cotyledon, S. longifolia, S. cochlearis, S. lingulata and S. l. lantoscana, S. marginata, Thymus azoricus, Sempervivum arachnoideum and Veronica prostrata.

Peat-loving plants are very few in number compared to lime lovers—barely 5 per cent. They are mostly shade plants, although a few may be grown in a sunny position providing there is plenty of moisture for the roots. The following are peat-loving plants, but require a half-shady position: Bruckenthalia spiculifolia, Bryanthus empetriformis, Cathcartia villosa, Dianthus alpinus, Dodecatheon Meodia, Gentiana Pneumonanthe, Shortia galacifolia, Erica carnea, E. vagans (these will also grow in sandy loam), Schizocodon soldanelloides, Meconopsis Wallichii. Many of the kabschia saxifrages will flourish in a sunny position, like S. sancta, S. Haagei and S. apiculata.

SOME LEGAL ASPECTS RELATING TO FENCES & TRESPASS

BY A BARRISTER-AT-LAW.

A COURT OF APPEAL CASE.

THE case of Buckle *v.* Holmes, which came before the Court of Appeal recently, contains legal distinctions of much importance to the general public, and particularly to the rural community.

THE LAW AFFECTING FENCES.

It is probably fairly well known to most agriculturists that, apart from certain statutes of special application, the owner of land is not bound, in the ordinary course of law, to put up and maintain fences around his land. If, therefore, an owner's cattle should stray on to the land of a neighbour, and are injured, that neighbour is not responsible for the injury, because he is not compelled to keep the cattle off. But, on the other hand, the owner who allows his cattle to wander off on to a neighbour's land will be liable for damage done by the cattle, since it is the duty of a person to see that his animals are kept within control.

A DUTY WHICH ARISES.

Consequently a kind of duty arises to fence so as to prevent cattle straying off the land but not to prevent them from straying on to the land. Yet, even so, the responsibility of an owner who fails to keep his cattle in is not a liability arising from his neglecting to fence, but from his neglect in allowing his cattle to stray. Therefore, provided he can keep his animals in by any other means, there is, strictly speaking, no duty cast upon him to put up fences, save in cases of special statutes previously mentioned, which do not affect the general rule of law. It is important to keep this condition of our law well in mind.

BOUNDARY FENCES.

For where there is a fence on the edge of adjoining land it would become entirely unnecessary for an owner to fence off his own land by putting up another fence. But if the fence of the neighbour whose land so adjoins falls into a state of disrepair, the owner of cattle will be liable for damage committed by his cattle which break through the fence and get on to his neighbour's land. Adjoining owners usually arrive at some mutual understanding as to fences upon such a boundary, and landlords, of course, often make certain stipulations with lessees and purchasers of land in relation to the question of fences and their maintenance. It may be added that a purchaser of land can always agree to erect and maintain a fence, but such a promise is only binding on him and cannot be made to bind subsequent purchasers from him. But a lessee can, of course, agree with his landlord as regards fences, and such an agreement usually binds both sub-lessees and assignees of the lease

FENCING OFF DANGEROUS THINGS.

An owner or occupier is always responsible, quite apart from statute law, for failure to fence off dangerous things on his land which are likely to prove a nuisance or danger to other people. So, therefore, if such an owner or occupier elects to make, say, an excavation near a public road, or near a private footpath over which the public are accustomed to pass, he will be liable for any injury or damage caused by his omission properly to fence such excavation. It may be mentioned, also, that by Act of Parliament provision is made, among other things, to fix the responsibility for neglecting to fence pits or shafts within 25yds. of a cart or carriage way upon the landowner who opens up such pits or shafts. Disused mines within 50yds. of any footpath must be likewise fenced.

LAW OF TRESPASS APPLIED.

The case of Buckle *v.* Holmes involved, of course, a different issue, and an examination of the law relating to trespass formed a substantial part of the judgment delivered in that case by the Court of Appeal. It is by no means easy for the average layman rightly to appreciate the true application of the law in connection with trespass without first arriving at some understanding of that side of our law now dealt with in regard to fences.

A REQUEST TO ALL OLD READERS

SOME of the older readers of THE GARDEN have pointed out that there are numbers of the fraternity of amateur gardeners throughout the British Isles, who have not read this paper. THE GARDEN is calculated to render them the best attention by giving seasonable advice on planting and sowing and by solving the problems and difficulties that at times beset all gardeners. Some of our contributors suggested a few weeks ago that an acceptable present to send a friend would be a copy of the paper for a year. It was a capital idea and one that we hope will bear fruit, but many of our older readers think that it went scarcely far enough, so they have suggested to us that a further appeal might be put forward. THIS IS THE APPEAL: That *every* reader should pass on the copy of the paper to someone whom they know does not take it in, but who would like to read it. Everybody has some friend whose hobby is gardening, yet seldom reads a paper about it! Readers of THE GARDEN will agree that such friends are the poorer for not making the acquaintance of our paper.

JOIN THE CIRCULATION CIRCLE AND PASS IT ON

If you become a regular reader of the paper, it will increase your interest in your garden because it is specially intended to help amateurs. Amateurs comprise the greatest number of gardeners. THE GARDEN is published every Thursday. It says what it has to say in plain language, free from ambiguity, so that the beginner cannot fail to understand. It is noted for the wealth of its good illustrations. As you will see, they speak for themselves.

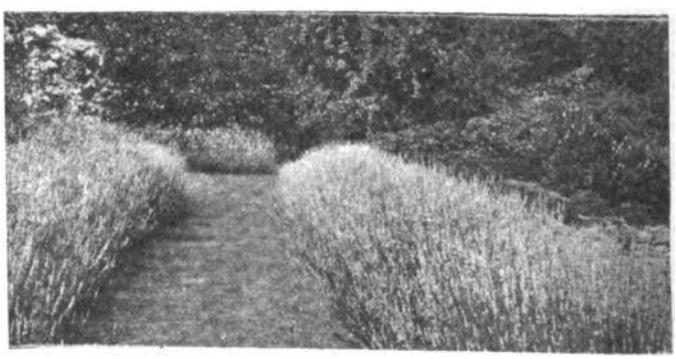
You may have failed last year with certain crops. It may not have been entirely "the fault of the season." Or some plants did not turn out quite to your satisfaction. Perhaps you have fruit trees that are not yielding what you think they should.

Remember THE GARDEN caters for all departments of horticulture. It is out to give the best advice, the best news, and the best service to a wider circle of readers. That is its policy. It will be pleased to be of service to YOU.

If you experience any difficulty connected with your garden—however small that garden may be—write to the Service Bureau giving the facts briefly, and they will suggest what should be done.

YOU CAN GIVE NO BETTER GIFT

to your friend, either at home, in the Colonies, or abroad, than a weekly copy of



THE GARDEN

It means 52 remembrances of friendship in the year

If you will fill in the form below, we do the rest.

SERVICE BUREAU.—*Continued.*

Unhealthy Freesias and a Remedy for White Fly.

I have to thank you for more than one letter of helpful advice. May I now ask you if you can tell me what is the matter with several pots of freesias which seem to be yellowing back from the tips of the leaves? They threw up strongly. A batch of young bulbs I am growing on in a box nearby are all right so far. Some of the affected plants are old ones I have grown on, others freshly purchased this year. They are in a greenhouse free from frost and have not been fumigated; other things growing near are all right. Secondly, can you tell me of any remedy for white fly that will not scorch plants? —C. M. A. P., Newbury.

Possibly the old freesia bulbs are defective, weak and do not root freely. If the bulbs are producing roots normally, the compost is not suitable, or there are wireworms at work on the roots. Both would cause yellow leaves. White fly continue to hatch from eggs for several days. One fumigation of the house might kill live flies, but in two days time more from eggs will appear. Fumigate every third or fourth day for a fortnight, and use Darlington's original auto-shreds.

Violets as Cut Flowers.

I shall be much obliged if you could tell me what to do to make cultivated violets (grown out of doors) live in water. I have tried soft and hard water, also putting them in a cool room, but it makes no difference. In a few hours nearly every one droops and dies. The wild violets will live in a floating bowl, but the long-stemmed varieties are hopeless.—A. G. C., Holbeach.

You should gather the violets early in the day and cut off the stems with a sharp knife, not scissors, which does not crush or bruise the sap vessels. Place a small tablespoonful of salt in a quart of water for keeping the violet stems in bowls or glasses.

The Culture of Lilium longiflorum.

I intend to go in for growing Lilium longiflorum giganteum. I should be much obliged if you can give me a little information on growing same. When should I plant them to have them in bloom in September and October? Could I grow them outdoors in the open soil and pot them up in the summer and put them under glass to bloom, or should I have to grow them in pots right through the season in glass houses?—W. Q., Guernsey.

You should be able to grow Lilium longiflorum giganteum quite well outdoors, but if you are growing for market purposes you would have to consider protecting the flowers from bad weather, as a spell of wet would certainly spoil them for market work. If you just want them for garden decoration, they should do perfectly with you if your soil is light and well drained. You could plant them out when you receive the bulbs or pot them up and stand them in cold frames, planting them out during the spring, when all danger of late frosts is past. You could not lift them from the open ground and pot them up for taking indoors, but you could pot them and plunge the pots outdoors all the summer, and then bring them indoors to flower. If you plant them outdoors they should—as far as we can judge your climatic conditions—naturally flower at the period you desire. If grown indoors they should be grown perfectly cool to flower at that time, but without actual experience of your conditions it is not easy to say how long they would take to flower, as our experience has been limited to the south and west of England.

OBITUARY.

Dr. N. Y. Lower.

ALL daffodil lovers will earn with sorrow of the death of Dr. N. Y. Lower, formerly of Presteign, which occurred after a lingering illness on November 20th at St. Blazey in Cornwall, where he had gone to live some months ago. Dr. Lower, who has been president of the Midland Daffodil Society for some seasons past, was a whole-hearted and enthusiastic devotee of the daffodil, and has been for many years a keen and very successful hybridist, as evidenced by the fact that he almost invariably carried off the chief honours in the most important seedling classes at the Birmingham and London shows of recent years.

He had built up one of the finest collections in the country, as, in addition to the best varieties of recent introduction and his own beautiful seedlings, he had acquired the stocks of many of the very best of the remarkable seedlings raised by the late Mrs. R. O. Backhouse of Hereford. It is hoped that many of his fine productions will yet find their way into our gardens. Such superb flowers of his raising as Royalist, Beauty of Radnor, Rewa, Clarion and many others have already achieved fame, and doubtless there are others of equal or greater excellence which have not yet been sent out.

He will be greatly missed at the daffodil shows, especially at Birmingham, where his magnificent exhibits were one of the main centres of attraction. His flowers were always splendidly grown and shown in superb condition. The work and enthusiasm which he contributed towards the development of the daffodil were a great stimulus and encouragement to all interested in the cult, not only on account of this, but because of his unassuming and most attractive personality his passing leaves a gap in the more intimate circle of daffodil people which cannot be filled, at all events on this side of time. G. L. W.

TRADE NOTES.

ALL keen gardeners should make a point of obtaining the R.H.S. Gardener's Diary for 1927, published by Charles Letts and Co. This diary has proved immensely popular in the past, and in its new and revised form should be found still more useful. Much valuable and helpful gardening information is given in its pages, while the diary is of a handy and convenient size for the pocket.

The wonderful success of Empire Packet Tobaccos produced by John Player and Sons has induced the Nottingham firm to offer to cigarette smokers a packet of Empire Blend Cigarettes. As a consequence of the preference on Empire-grown tobaccos these Player's Empire Navy Cut cigarettes will be retailed at 10 for 5d., and splendid value they are, too.

In our note on the new "Beco" rose bowl loud-speaker in our last week's issue, it was stated that the manufacturers were Messrs. W. Darlington and Sons, Ltd. This firm, however, only engage in sales. The sole patentees and manufacturers are "Beco," the British Electrical Sales Organisation, Strand, W.C2. We regret the mistake.

CATALOGUES RECEIVED.

Messrs. T. W. Cole and Son, Westwood Nurseries, Peterborough. A long list of new and choice chrysanthemums of all types as well as show and zonal pelargoniums and fuchsias.

Messrs. Frank Cant and Co., Braiswick Rose Gardens, Colchester. A well classified descriptive list of roses.

Messrs. H. Merryweather and Sons, Southwell, Notts. Roses, fruit trees, shrubs, climbing plants.

BULBS

We invite immediate application for our

JAN 5 1927

HORTICULTURAL ROOM LIBRARY

THE GARDEN

THE AMATEUR GARDENERS' PAPER

Vol. XC.—No. 2873 Saturday, December 25th. 1926 Price TWOPENCE

CHRISTMAS decoration often presents a difficulty to the housewife who is anxious to make as good a floral display as possible at a period of the year when flowers are very scarce. Holly is a great stand-by as well as having a special significance at this time of year. With its dark shining leaves and contrasting clusters of its rich red berries it makes an admirable subject for vase decoration, especially when used in association with late blooming flowers, such as chrysanthemums. Such combinations look as well, if not better, under artificial light than by daylight, and make very effective interior decoration.

JOIN THE ELITE and go to Hewitts the horticultural specialists who have made such a sensation throughout the country with their

DELPHINIUMS AND GLADIOLI.—You will be well advised to write for our catalogues of Seeds, Delphiniums, Roses and Gladioli. We offer only one quality—the best! May we add your name to our large list of delighted customers? —HEWITT'S, Solihull, Warwickshire.

IRON AND WIRE FENCING FOR GARDENS.—Ornamental Iron and Wirework of every description. Catalogue G. 156. Iron Fencing and Tree Guards. Catalogue G. 65. Wood and Iron Gates. Catalogue G. 163. Kennel Railing. Catalogue G. 86. Poultry Fencing. Catalogue G. 70. Ask for separate lists.—BOULTON AND PAUL, LIMITED, Norwich.

ORDER TENNIS COURT FENCING NOW.
Complete enclosure, 120ft. by 60ft., for one Court, 9ft. high, with Iron Standards, Gate, Strand Wires, ready for erection, £34. Carriage paid to stations in England and Wales. Other sizes in proportion. Write for special Leaflet to Dept. FP/G., BOULTON AND PAUL, LIMITED, Riverside Works, Norwich.

AUSTRIAN PINE, DOUGLAS FIR, SCOTS PINE. Stout well shaped trees. Also Fruit Trees in great variety. Write for descriptive catalogue.—THE FOREST AND ORCHARD NURSERIES, LIMITED, Milbury Heath, Falfield, Glos.

HAVE YOU BOUGHT YOUR COPY OF "FARRER'S Last Journey"? by E. H. M. Cox. Demy 8vo. Fully illustrated. 18/- from all booksellers, or 18/9 post free from the publishers, DULAU AND CO., LIMITED, 34-36, Margaret Street, London, W.1

DOBBIE'S 1927 CATALOGUE AND GUIDE,
144 pages, 229 illustrations; free to all readers. Please mention "THE GARDEN," when writing.—DOBBIE & CO., LTD., Edinburgh.

SEWAGE DISPOSAL FOR COUNTRY HOUSES.—No emptying of cesspools; a perfect fertiliser, no solids; no open filters; perfectly automatic; everything underground. State particulars.—WILLIAM BEATTIE, 8, Lower Grosvenor Place, Westminster.

CHEAP GOVERNMENT WIRE ! ! !—Ideal for training fruit trees, peas, beans, hops, arches, greenhouses, tomatoes, logans, tying, fencing, etc. Strong, flexible, steel-stranded and waterproof covered. Several thicknesses from 19/6 per mile (full 1,760yds.). Small lots quoted. Post card to-day for free samples and list of 300 bargains.—GREEN'S GOVERNMENT STORES, 69, Albert Street, Lytham.

ROCK PLANTS AND SHRUBS.—Over 300 varieties in stock. Descriptive Catalogue free. Also Herbaceous Plants and Roses.—HODSONS, LIMITED, 58, Castle Gate, Nottingham.

RIVERS' FRUIT TREES, ROSES, VINES,
Figs, Oranges and Orchard House Trees are of first-class quality and a large and select stock is always on view. Inspection invited. Price list post free, on application.—THOS. RIVERS AND SON, LIMITED, The Nurseries, Sawbridgeworth, Herts.

PRIOR'S COLCHESTER ROSES, Fruit Trees, Gladioli, Dahlias, Carnations, Herbaceous. Catalogue containing cheap collections free.—D. PRIOR AND SON, LIMITED, Colchester.

WELLS' CATALOGUE OF CHRYSANTHEMUMS, now ready. Post free on application. Please note change of address.—HAROLD WELLS, Peaslake, Gomshall, Surrey.

A GARDEN EVER IN BLOOM is easily and economically achieved by planting my Hardy Herbaceous Roots. Fully illustrated list post free. Satisfaction guaranteed or cash refunded in full on return of plants.—H. E. POLLARD, Nurseries, Evesham.

YORK STONE PAVING, for Garden Paths and lily ponds; rectangular or crazy for rustic work; steps and wall coping; rockery.—GEO. VINT AND BROS., Stone Merchants, Idle, Bradford.

FIBROUS YELLOW TURF LOAM.—Catalogue free.—A. B. JOHNSTONE, Cranleigh.

FOR EVERGREEN SCREENS OF QUICK growth with flowers from May to Xmas, the Alberic Barbier Climbing Rose, 9/- per dozen.—BEARERS, Norwood Hill, Horley.

LOAMS FROM OLD HAMPSHIRE
PASTURE or Woodland, rich and full of fibre, heavy or sandy. Quotations free on rail Chandler's Ford Station.—HILLIER AND SONS, Nurserymen, Winchester.

NEW AND RARE LILIUM SEEDS, 1927.
Novelties in Sweet Peas, Antirrhinums and Alpines. Catalogue post free.
E. V. ROGER, Seedsman, Pickering, Yorks.

BEAUTIFUL "PANTHER" LILIES (L. pardalinum).—A large quantity of surplus home-grown bulbs. They succeed anywhere. 6 for 5/-; 1 dozen, 8/6; 100, £3 3s. Cash with order. Carriage paid.—Mrs. LLOYD EDWARDS, Trevor Hall, near Wrexham.

FIVE VINES FOR SALE, 5 years old 2 Gros Colmar, 2 Black Hamburg, 1 Unknown. Best offer. —Apply, Mrs. BRIAN TINKER, Meal Hill, New Mill, near Huddersfield.

A Superb Present

ENGLISH GARDENS

By H. AVRAY TIPPING

Large folio. With over 550 *illustrations* - - **£3 3s.**

MR. AVRAY TIPPING is a past master in garden design, and is himself a practical gardener. As an authority on family-social history and in particular on horticultural history, he is without an equal. The volume contains a long historical introduction on English gardening, and then proceeds to illustrate fifty-two gardens of different types.

Notes from Maidstone.

COOKING APPLES.

All Apples may be cooked, but not all are edible. Some are pasty and flavourless, others brown and woody. We can thoroughly recommend Golden Noble for autumn use, this cooks a clear amber yellow, and Thomas Rivers, in use till December, of unique fragrance. Of these, beside the usual forms, we have some extra large pyramids, 6ft. high and well developed, at 15/- each.

VOL. XC.—No. 2873 DECEMBER 25, 1926. PRICE TWOPENCE.

NOTES OF THE WEEK.

The Past Season.

ON the whole, the year 1926 has been kind to gardeners. The flowering seasons have been distinctly good, particularly in late summer and autumn, until the sudden deluges drenched the country in November. Fruit, on the other hand, has been patchy; small fruit has mostly been excellent and, on the whole, fairly free from disease, although pests like gooseberry mildew have been widespread in certain areas. Other fruits yielded abundant crops all over the country and the yield of plums was, if anything, above the average. Counteracting these heavy yields came reports from all over the country from north to south of the bad crops of apples and in some cases pears. Apples were especially bad, and it is a little difficult to account for their general failure this year, unless it can be put down to the protracted period of frost and cold winds which all gardens experienced during April and May at the time of blossoming and fruit-setting. Next year, we hope, may hold better in store in the shape of bumper crops of apples, our staple fruit, for all amateur gardeners.

Vegetable crops came up to the usual standard. There were no widespread epidemics of disease such as occur every few years. Such epidemics are becoming rarer and rarer with our increasing knowledge of the plants themselves and their wants and, secondly, of the diseases. Only in certain districts were potatoes attacked by the deadly blight disease, due to a short spell of rainy weather in the early summer. Gardeners who cultivate a small vegetable patch had certainly nothing to complain of about the season.

The season has in general been very kind to all flower gardeners. The weather, all the year round, has been consistently good and very kind to all flowering shrubs, herbaceous plants and rock plants. The flowering display in the majority of gardens up and down the country has been a brilliant one and has lasted over a long period from early spring right on until late November. The magnificent collections of plants staged at the various horticultural shows throughout the country testify to the high standard reached in flower production this year. Improvement has been registered in many garden plants and many novelties of note have made their appearance in the various races of our garden flowers. Among them the gladiolus stands out pre-eminent, and in the coming year it will, no doubt, add still fresh laurels to its name and attract many new admirers. Many new varieties of tall herbaceous subjects have seen birth. Phloxes, perennial asters and delphiniums have all added new names to the already long lists of modern varieties of their admirable races, but whether many of this year's novelties have come to stay and grace our gardens in future years is another story. No doubt many will die an untimely death, but others again will catch the favour of enthusiastic gardeners. No matter, the trend is in the right direction and all amateur gardeners owe a debt of gratitude to all those engaged in the cultivation, development and ultimate improvement of our garden plants.

This year has seen an increasing popularity of ornamental flowering and fruiting shrubs for use in the small garden, and once several of these newcomers to our gardens become more widespread they will become still more appreciated for decorative garden effect. The great majority are handsome plants, hardy in nature, fairly easy to grow and easy to look after, and thus eminently suited for the amateur.

THE GARDEN itself has recorded a change in the past year, and it is one which, we feel sure, has been much appreciated, judging from the many congratulatory letters we have received from readers. We hope that during the coming year readers will come forward with their difficulties and suggestions and assist us in every way possible to make THE GARDEN the amateur gardener's most valued asset.

We wish you, our readers, a very merry Christmas and a good gardening New Year.

HAVE YOU

- ¶ *Renewed your annual subscription to* THE GARDEN *?*
- ¶ *Cut down, after flowering, your late greenhouse chrysanthemums and placed the pots in a cold frame so that they produce cuttings ?*
- ¶ *Studied the new seed catalogues and made out your seed orders ?*
- ¶ *Examined your pots of bulbs and uncovered those which have made 2ins. of growth ? The pots should be taken into a greenhouse in a few days.*
- ¶ *Looked over your stored fruits and onions and removed any decaying specimens ?*
- ¶ *Dressed all sour soil with ground garden lime at the rate of 6 oz. per square yard ?*
- ¶ *Dug in soil fumigants into the ground under your fruit trees which are infected with pear midge, currant moth or gooseberry sawfly ?*

Horticultural Societies.

WE are sure that many of our readers are interested in their local horticultural societies and flower shows. The latter are useful not only as occasions on which a friendly rivalry is shown between growers of plants under somewhat similar conditions of soil, climate and so on, but also as proving what can be accomplished in the way of growing fine flowers, fruit and vegetables. To a careful observer much can be learned at a local flower show. The results of the best of the season's crops are seen; friendly advice can be asked for and given; probably some produce or flowers are shown which are not in common cultivation in the neighbourhood which helps to suggest new plants for one's garden. The same interest is attached to meetings of horticultural societies.

We realise that it is sometimes difficult for societies to give due publicity to their meetings and shows, and so it has been decided to include in each issue of THE GARDEN a diary of events for the week following that of publication. In order to make this diary as complete as possible WE ASK ALL SECRETARIES OF HORTICULTURAL SOCIETIES, LARGE AND SMALL, TO SEND US A LIST OF THEIR MEETINGS AND SHOWS FOR THE COMING SEASON. By this means we hope that in a short time all readers of this journal will get the habit of looking up the dates of horticultural events in their respective districts.

The Crossword Prizes.

THE two prizes of One Guinea each, offered to the readers who sent in the first correct solutions opened to THE GARDEN Crossword No. 4, which appeared in our issue of December 11th, have been awarded to

Mr. A. J. Harris,
Brambledown,
Cranford Avenue,
Exmouth, S. Devon.

and

Mr. S. R. Nevard,
66, South Street, Colchester.

To each of whom a cheque for that amount has been sent.

A MINIATURE WATER GARDEN

ONE of the most attractive features in connection with a rock garden is a miniature water garden. Quite the simplest way of forming the pool is to use a tank or a barrel which will give an inside depth of at least 18ins., or more if possible. An oil or liquor cask is excellent for the purpose, and the barrel should be carefully sawn in two. Each barrel will, naturally, give one a couple of pools if space can be found for these. In the case of an oil cask the inside should be charred with fire before it is used. The barrel is sunk level with the soil and around it the ground is excavated to a depth of 15ins. The bottom and sides should be puddled with clay until they are perfectly watertight. This space should preferably be filled in with a compost formed of equal parts of fibrous loam and peat. In place of the loam any good garden soil may be employed, and if this is mixed with a third part of decayed leaves and a similar amount of peat, quite a suitable medium is secured. In the surrounding portion of the little water garden the soil should be carried to the height of from 4ins. to 6ins. above the level of the water. This will enable some of the more delicate semi-aquatics to hold their own, for if these are placed on the higher levels they will not be in so much danger of being overshadowed by the more vigorous subjects. In addition the crowns of these plants will be comparatively dry in winter, and this is a distinct advantage in many cases.

Of course, the edge of a barrel gives a hard and unattractive outline, and this can be relieved by the formation of a rocky edging. Some of these rocks might overhang the water a little, and in between them pockets of soil will provide rooting places for ferns and other plants. Where several tubs are employed arrange the levels so that after leading water to that which is highest all the others will benefit by the stream trickling from one to the other.

Water Lilies for Tubs.

In tubs only the dwarfest water lilies can be grown, as the strong-growing varieties will fill the space right out and end up by hiding the water altogether. Thus the graceful effect of these beautiful flowers is largely lost. Suitable nymphæas for tubs are N. odorata minor (pumila), N. pygmæa alba and its variety Helvola. The first two named are white flowered and the last has beautiful sulphur yellow blooms. Some of the smaller forms of the coloured Laydeckeri nymphæas are also very suitable for the tub water garden, and the best of these are liliacea, fulgens and rosea. A few other good plants for the barrels include Aponogeton distachyon, Pontederia cordata, Sagittaria japonica plena, Menyanthes trifoliata, Orontium aquaticum, Typha minima and Scirpus zebrinus. In planting the aquatics in the tub some of the soil prepared for the outlying border should be placed in the bottom. Arrange this in a mound 6ins. or 8ins. high with its summit well to the centre of the tub. Do the planting while the tub is empty and then carefully fill in the water so as to create as little disturbance as possible. One water lily will be sufficient for each tub.

Outside the tub one can plant such subjects as Caltha palustris flore pleno, Mimulus cupreus, Primulas rosea, japonica, sikkimensis and pulverulenta, Trollius Orange Globe, Myosotis palustris, Helonias bullata, Cypripedium spectabile, Ranunculus aconitifolius flore plena, astilbes in variety, dodecatheon, media, trillium and Iris Kæmpferi.

A SMALL WATER GARDEN OF MORE FORMAL DESIGN.
Here full use has been made of water lilies and suitable moisture loving plants.

Larger Forms of Water Gardens.

One of the accompanying illustrations shows a small lily pond encircled by a narrow path made of broken flagstones the cracks of which are filled in with soil and surfaced with fine sand on purpose to encourage the growth of velvet-like moss. In the larger crevices of the path Silene acaulis, Arenaria balearica and Dianthus alpinus have been planted. The pond is sheltered on the north side with various trees and shrubs, and growing at the water's edge we find Menyanthes trifoliata (the bog bean), Butomus umbellatus (the flowering rush), Ranunculus Lingua, Caltha polypetala (the many-petalled kingcup) and various other plants which are not too rampant in habit. The water lilies are all small-growing varieties which flower well year after year.

A formal lily pool of rectangular design is seen in the second illustration. Here the lily pool is made in the centre of a small sunk lawn which is about a foot lower than the surrounding portion of the garden. The pool is edged with square slabs of paving stone, and on the surface of the water are floating two groups of nymphæas, one white, the other pink. In the corner of the pool is growing a mass of giant spearwort (Ranunculus Lingua grandiflora) mingled with the foliage of the flowering rush. On either side of the stone seat are bold clumps of Funkia Sieboldi, which is most striking with its large grey-green leaves and its soft lilac mauve blooms. Although the whole arrangement is on a small scale, yet the effect is charming, harmonising perfectly with the immediate surroundings.

AN ATTRACTIVE POOL WITH DWARF WATER LILIES IN VARIETY AND OTHER AQUATICS PLANTED ROUND THE MARGIN.

THE FLOWER GARDEN

Achilleas for the Border and Rock Garden.

THE yarrows constitute a large family, some of which quoted in catalogues are not worthy of cultivation, but those mentioned in these notes are suitable either for borders, the rock garden or for planting in retaining walls; in fact, they are the cream of the group or genus. Those suitable for the herbaceous border include A. E. Ptarmica The Pearl, a beautiful double white attaining a height of about 2ft. It is very effective, and most suitable for cutting purposes, and no border should be without a small group of this desirable subject. Another fine double white is known as Perry's White, and A. Millefolium Cerise Queen is a pleasing contrast to the white species. A somewhat strong grower is A. Eupatorium, which has yellow heads of flowers and grows about 3½ft. in height. This, however, is not recommended for the small border, but for larger gardens it will prove useful at the back of dwarfer plants.

The rock-loving representatives of the genus constitute an interesting group, many of which are also suitable for placing at the front of the herbaceous border, especially those with an irregular front line running parallel with a gravel walk. Here the wonderful leaf beauty of many achilleas is most effective both before and after flowering. The white and silvery patches produce delightful contrasts with other green subjects that may be near them, either on the rock garden or border. The dwarf achilleas are often spoilt by planting them in partial shade and a too rich rooting medium. Under these conditions the full beauty of the foliage is never revealed, while the flowers are not freely produced. Hence sunny positions should be chosen, and if the soil is poor, stony and devoid of manure, good results will be obtained.

Most of the flowers are white, but in spite of this the following dwarf kinds are all worthy of cultivation. One of the best, which is of hybrid origin, is A. Kellereri, which makes loose tufts of linear silvery leaves with branching stems of white flowers. Quite a gem for the rock garden or wall.

A. argentea is another fine species of the silvery section, very neat and compact in habit; while A. serbica comes under the same category. It flowers excellently in a rock wall or fissure, but in the border on level ground I have found it less beautiful. A good and attractive small plant is A. tomentosa, quite of carpeting habit, forming dense patches of woolly green foliage and heads of bright golden blossoms. The achilleas bloom during the spring and summer months, and may be planted at any time from now till the early spring. When rearranging the borders or adding new plants, the achilleas, particularly the Pearl section, should certainly be given thought and consideration.—T. W.

A Handsome Border Plant.

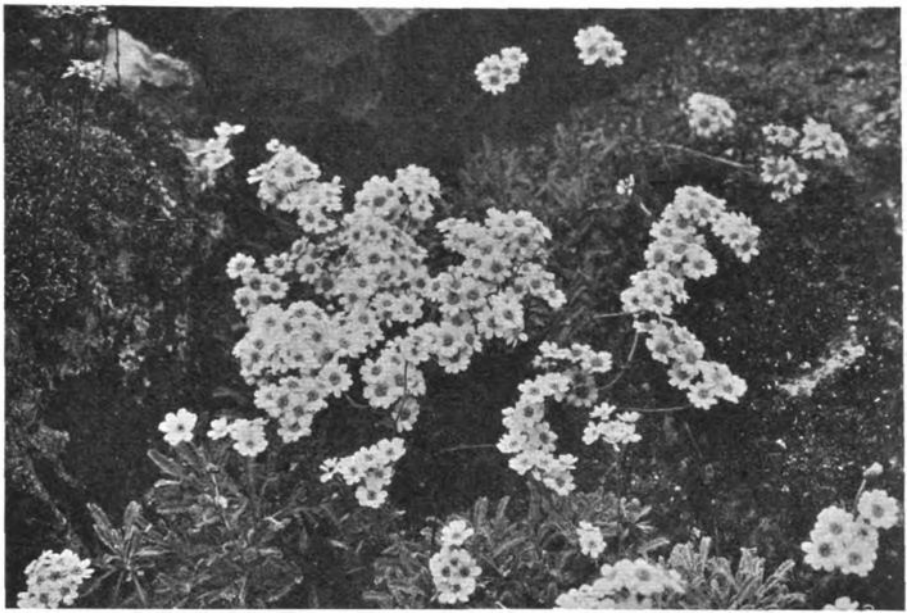
THE illustration gives a good idea of the striking effect that can be produced by Salvia nemorosa in the flower garden. Much better and more showy results are obtained in this way than by placing isolated examples here and there the whole length of the border.

S. nemorosa is a variety of virgata, and it is a handsome hardy herbaceous subject which should be planted liberally, as it is one of the most valuable border plants.

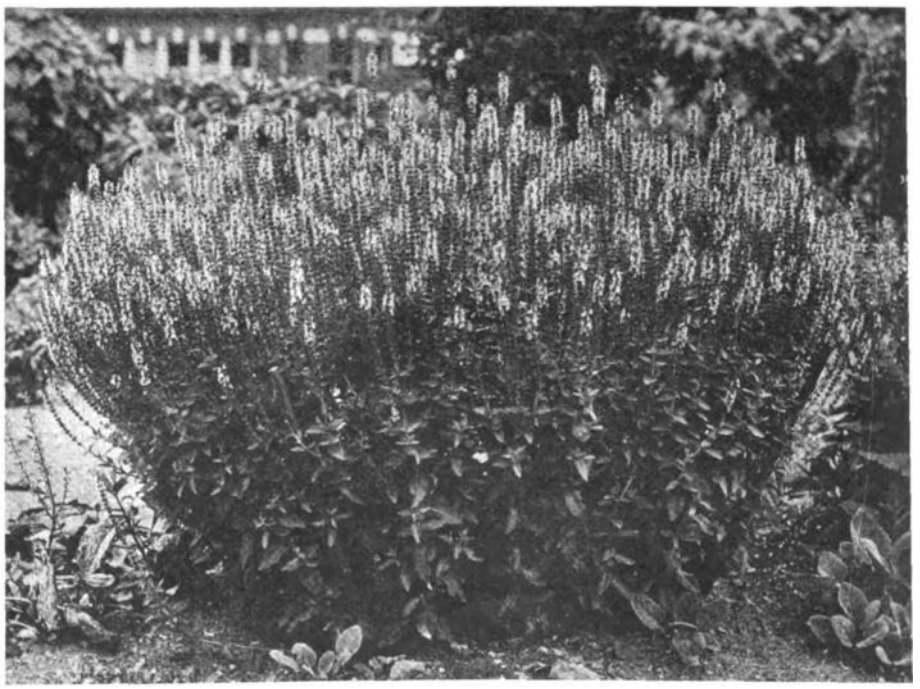
The height of the plant is about 2ft., and the strong erect spikes of purple flowers with showy crimson-purple bracts are freely produced in early summer. After the spikes are past their best they may be cut back to half their length, when young spikelets will continue the flowering period till the autumn. There is also a white form known as alba. —T. W. BRISCOE.

Hollies for Small Gardens.

THE common holly is not for small areas; it looks its best, in shaggy unpruned glory, in a wood or large shrubbery, and it never seems at home when cribbed and confined. Some of the refined variegated forms also seem to be most satisfactory, too, when allowed to grow at will to goodly size, especially when they are of a loose-growing type. Those which the man with a small garden must choose are of neat compact habit and, again, they must be bright so as to show up well under the disadvantage of restricted space. A charming variety for our purpose is Waterer's Gold Striped, which seldom exceeds 4ft. in height. The Golden Milkmaid is another very bright sort, curious and attractive, while not too rampant; Silver Milkmaid is very much similar; angustifolium, especially the variegated varieties, will also serve; Silver Queen, Golden Queen and Moonlight Queen, while free growing, can by a little pruning be readily kept in bounds. These last three, as well as Golden King, ovata aurea and angustifolia variegata, also look quite well



THE SILVERY LEAVED ACHILLEA ARGENTEA A NEAT SUBJECT FOR THE ROCKERY.



SALVIA NEMOROSA WITH ITS ERECT SPIKES OF PURPLE FLOWERS MAKES A FINE BORDER PLANT.

Digitized by Google

when hard clipped. The hedgehog holly, a dwarf form, very full of spines, is quite effective in appearance when carefully planted. Perneyi is of neat growth and habit, fine for a lawn. There are several weeping hollies not very often seen in cultivation, but undoubtedly pretty and most effective in appearance. The best with me are the golden-edged and silver-edged weeping hollies. Amateurs who let the shrubs grow at will need not worry at a free but judicious pruning about this period when decorative stuff for Christmas is in demand; only, my experience urges me to advise that the pruning be done by the owner and not by all and sundry. After Christmas mulch some leaf-mould, humus or rich loam round trees, and this will keep them healthy and fresh.—LANARKSHIRE.

The Winter-Flowering Jasmine.

AT the present time this charming plant is in full bloom, and no other shrub can produce such a glorious sight at this season. In habit it is somewhat rambling and is best planted against a wall, where its main growths can be made secure against wind. The position appears to be of little consequence, because I have seen it flowering freely on all sides, especially on a wall facing east. Other positions will occur to the owner of a garden, however small, where this showy semi-climber would brighten up the dull period of the year, while sprays cut when the flowers are still in the bud stage, open splendidly in a warm room. J. nudiflorum will attain a height of 12ft. to 16ft., and produce a large number of long pendulous shoots which are eventually covered with bloom. The bright yellow flowers are ¾in. to 1in. in diameter, and they are produced singly on short stalks when the plants are devoid of leaves. It is a native of China, from whence it was introduced in 1844.

Many amateurs fail to get the best results from this jasmine owing to pruning at the wrong time. Directly the flowering season is passed, the necessary pruning should be carried out, and not in the autumn as practised by many. The object of pruning is to encourage new growth, which should be vigorous shoots by the autumn. Cut out any old branches not required and other growths are pruned back to near their base. Annual pruning immediately after flowering will remedy this, and produce a healthy specimen capable of showing what a desirable plant the winter jasmine can be.—B.

Crocus Tournefortii.

THIS is a charming little autumn-flowering crocus to grow in small pots, and in a cold frame it is also making a pretty show at the moment (November 19th). The colour of the flower is a pale blue-mauve, the anthers white and stigmata orange; but its great merit and the quality that differentiates it from all the other autumn species, is that when the flowers open they remain wide open, regardless of lack of sun, so that a thickly planted little potful gives a charm to the very dullest of November days.—F. HERBERT CHAPMAN.

THE SMALL ROCK GARDEN

The Smaller Plants to be Grown.

WE now come to the gems of the rock garden, the tiny plants, mostly high alpines, dainty and floriferous, which are the joy of so many gardeners. In the following notes we shall confine ourselves to a selection of those which are of easy cultivation—given plenty of sunlight and drainage—and we shall reserve the most important group, the saxifrages, for a separate chapter. To take, first of all a number of characteristic things which ought not to give any trouble at all: Arabis Sturii is one of the best of its numerous group, small and white-flowered, forming a pleasant patch. Aster alpinus, the alpine Michaelmas daisy, is quite a gem, with big single flower-heads of purple and gold. The cyclamens are largely alpine in habitat, and a few of them will give little bits of bright colour when the rock garden is otherwise dull. Some of the smallest of the pinks are very dainty and quite easy, such as Dianthus arvernensis, microlepis, subacaulis. Erinus alpinus, with its tufts of pretty leaves and purple flowers, is highly useful, and is a great plant for an old wall, where it will sow itself freely. Geranium argenteum is most choice, with silver leaves and big pinkish blossoms. Globularia cordifolia, the smallest species of its group, makes a mat of dark green leaves dotted with blue flower-heads; it has a still smaller variety, nana. Gypsophila cerastoides is a tiny gypsophila, making a close hairy tuft bearing very attractive white flowers with pink veins. Hacquetia Epipactis is a quaint little umbellifer, appearing very early in spring, and gold in colour. Hutchinsia alpina is very good, with minute pinnate leaves and snow-white flowers. Hypericum reptans is a joy, forming a flat sheet of foliage with huge golden blooms lolling all over it. In Petrocallis pyrenaica we have a purple-flowered tiny draba, very minute. The large group of sedum may be represented by spathulifolium (preferably the var. purpureum, a most valuable rock plant); while for a very dry spot, or an old wall, S. dasyphyllum and the mealy-leaved S. brevifolium are valuable. Silene acaulis, our native cushion pink, forms a mound of fresh green with pink stars of blossom: but in the garden it is never covered with bloom as we see it on the mountains. Lastly, Tunica saxifraga produces annually a tangle of spidery stems clothed with rosy flowers—a light and graceful plant.

To take now a few good things of less robust constitution and needing a little care in planting and tending—though not actually difficult under reasonably favourable conditions—we cannot do without an androsace or two; and A. carnea and its varieties are, perhaps the most satisfactory. For a dry, warm corner and light soil one of the most delightful of all rock plants is Asperula suberosa (= Athoa), a tiny woolly thing with the daintiest clusters of pink flowers. The smallest of the erodiums, E. chamædryoides (= Reichardii), forms a little rosette of leaves among which rise the pinkish flowers. The beginner will not have gone far before he will long to possess a ramondia or haberlea, those beautiful purple-flowered gesneriaceous plants. They are not really difficult, if one can give them a damp corner: plant them there in a vertical chink of the stones in leaf-mould, and they ought to give no trouble. Another plant that many covet is the edelweiss, Leontopodium alpinum, which is quite easy in sun—but beware of slugs. And no one who has seen the soldanellas peeping out of the snow on the Alps can resist the temptation of trying to grow them. They are not hard to keep alive—in shade in a leaf-mouldy soil—but there is, alas! no golden rule for getting them to flower. Then there are two most delightful alpines, both bad perennials, but which with luck will sow themselves and flourish—at least for a time; these are the alpine toadflax, Linaria alpina, and the alpine poppy, Papaver alpinum—both in the very front rank of alpine gems. The many tiny primulas are mostly for the beginner only a source of burial services; perhaps P. marginata is the easiest, in half shade—a very delightful plant. And if you can keep slugs away, the wahlenbergias are beautiful things to have—there is a goodly choice of them; try dalmatica, pumilio or graminifolia.

R. LLOYD PRAEGER.

(To be continued.)

ASTER ALPINUS IS ONE OF THE GEMS FOR THE SMALL ROCK GARDEN.

THE BUSY MAN'S PAGE

When the Early Bulbs Have Flowered.

MANY people have an idea that bulbs which have been forced into flower at an early date are of no value afterwards. This is quite a mistake, for, with reasonable treatment, these bulbs can be relied upon to give some show of blossom next season. After the flowers are over, remove the flower spikes, but do not interfere with the leaves. If the bulbs are in soil they may be allowed to grow on until the foliage begins to turn yellow; then water should be withheld and the bulbs allowed to ripen in a sunny position. Where the bulbs are growing in fibre, replant them in pots or boxes of soil, or even in a sheltered border out of doors. These bulbs are not good enough for pot culture again or even for any outdoor position where reliability is essential. The best way is to plant them in some odd border, perhaps in the kitchen garden, where they will produce flowers that are useful for cutting. Hyacinths deteriorate most, but, even with these, the graceful little spikes of bloom are well worth having.

Lilac Suckers.

OWNERS of lilac bushes often find that the plants do not flower very well and, more often than not, the cause is to be found in the masses of suckers which have been sent up. To produce good heads of flowers it is necessary that lilacs should have vigorous well ripened shoots, and such a condition cannot be expected while so much of the food material is being wasted on suckers and weakly branches generally. All suckers from the rootstock must be pulled away if possible from the roots, and it also pays to remove a fair proportion of the weak inner shoots of the bush. This will result in additional vigour to the remaining branches and better ripening of the wood.

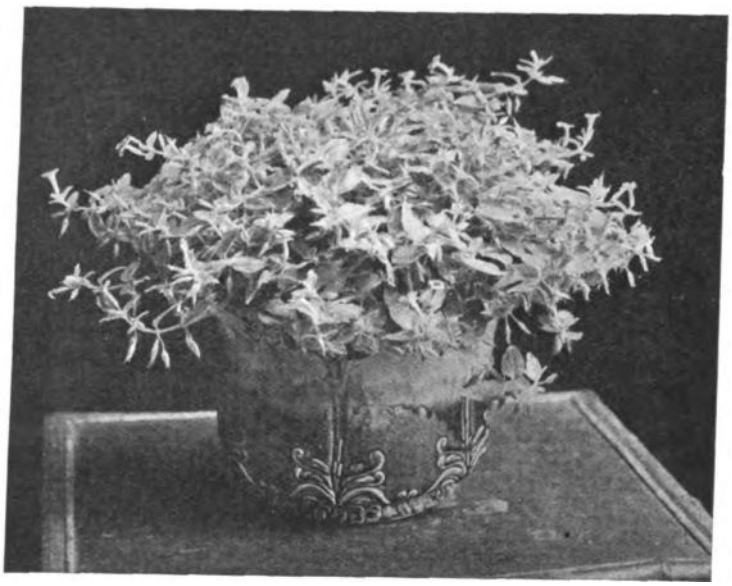
Protecting Water Pipes from Frost.

IN sharp weather the water pipes leading to taps in the garden are likely to freeze. To prevent this the pipes should be protected with some non-conductive material. The common plan of wrapping strips of sacking round the pipe is not very good, for this soon becomes saturated with water, so that when frost does come the pipe is really encased in ice; then the water inside will freeze more readily than if there was nothing round the pipe at all. A much better plan is to twist hay into tight bands and wind these round the pipe. If the hay is tightly twisted it will resist the rain to a remarkable extent, and, in a dry state, hay is a very poor conductor. If a pipe does freeze it is a good plan to thaw it out as soon as possible. Remove the hay bands and apply cloths wrung from hot water round the pipe, and the water soon flows again. During a spell of keen weather it is really wise to thaw out the pipe each morning (if this is needful), as when the ice is allowed to remain in the pipe for a couple of sharp nights the water will probably not flow again until the thaw comes.

Burst pipes are soon in evidence with the coming of milder weather. If, as often happens at such times, a plumber cannot be secured at once, a very good repair may be effected in this way: Cut strips about 2ins. wide from the old inner tube of a cycle or car tyre. Then wind these round the damaged area of the pipes. Stretch the rubber when winding, so that it grips the pipe well and complete the business by tying with strong twine. A repair of this nature will last for weeks, and it is quite possible to use the water supply without fear of leakage.

Mimulus for Pot or Basket Decoration.

MIMULUS makes a useful plant for hanging flower pots. The ease with which it may be raised from seed and its rapid growth make it specially suitable for the amateur.



MUSK MAKES AN EXCELLENT DECORATION IN EITHER POTS OR BASKETS WITH ITS BEAUTIFUL FOLIAGE AND RICHLY COLOURED FLOWERS.

From seed sown last January in the vinery, plants now measure a foot across. These were allowed to flower during the early summer in 48s. pots, and after flowering were cut down and repotted, when they soon became a mass of shoots. Some have just been put into large hanging pots and the drooping shoots completely clothe the pot. Many varieties will be found suitable for this purpose with their large-sized and well coloured flowers. The plants may afterwards be propagated by division.

Washing the Roots of Plants.

PLANTS which, for no very clear reason, seem to be unhealthy often benefit a great deal by having their roots washed. This applies to perennial species of all kinds and also to many of the smaller flowering shrubs like azaleas, tree peonies, etc. Quite often the cause of the poor development is due to the fact that the roots are infested with some insect or other pest. In such cases the plant should be lifted and its roots placed in a pail of water, rain or spring water being the best. The specimen may be quite safely left with its roots immersed for twenty-four hours or even longer. This will have the effect of drowning any pests that may have attached themselves to the roots. Finally, the plant should be set out again, and it is usually an advantage to put it in a new position. Even if this is not possible, great benefit will practically always arise from the washing of the roots.

Preparations for Early Spring Work.

THERE is much that can be done now under cover—in a greenhouse, a potting-shed or other outbuilding, that will help forward the actual work connected with the garden early in the new year. In town and suburban gardens pea and bean stakes are difficult to obtain, so all existing stakes should be examined now, the decaying ends that were in the soil during the summer cut off and broken ones used for fire lighting. The sound sticks should be tied into neat bundles and kept dry. Used with a few new ones next summer they will do good service again. New labels should be made and tied into bundles, graded as to size, the large ones for vegetables, the smaller and neater ones for flowers. Pots and pans should be washed and stored in a dry place; it is much easier to remove soil from them now than in spring when drying winds prevail. Mend seed boxes where they need it and make new ones. Heaps of exposed sand and soil should be covered from this date. Examine the garden tools, sharpen and clean them, not sparing the oily rag. Take stock of all tools and buy new ones at once if such are needed. Paint wheel barrows and hand carts, ladders and steps, keeping all these tools in a dry place.

Stopping Decay in Trees.

MANY an ornamental tree might be saved from rapid decay if timely attention was given in the early days of the trouble. To fill up the holes in the trees there is nothing so good as Portland cement. Before using the cement the decayed portion must be thoroughly cleaned out, all rotten parts being removed. It is essential that the cement should be able to get hold of sound wood, otherwise the decay will continue after the filling of the opening. Select a dry day for the business and let the cement be rather on the stiff side. Finish off the top carefully so that the surface will throw off rain, making sure that there are no positions where water could settle. When properly used the cement stops the moisture from going into the affected parts and arrests decay. Some trees split badly down the middle, and into the crack the moisture will penetrate, causing rotting. Here an iron band bolted together may be used as a clasp to prevent further injury, and the opening should be completely filled in with cement.

How to Rid a Pond of Green Scum.

THIS vegetation may be destroyed by adding copper sulphate to the water at the rate of one grain of the chemical to every gallon of water. The chemical may be tied up in a canvas bag, which is drawn through the water until its contents is dissolved. Another way is to mix the copper sulphate with water and then syringe the solution over the affected areas. Two or three applications may be needed during the year. When the chemical is used in this strength it will not harm gold fish or the legitimate plant occupants of the water garden. After treating the water with the copper sulphate it is as well to keep animals away for a few hours.

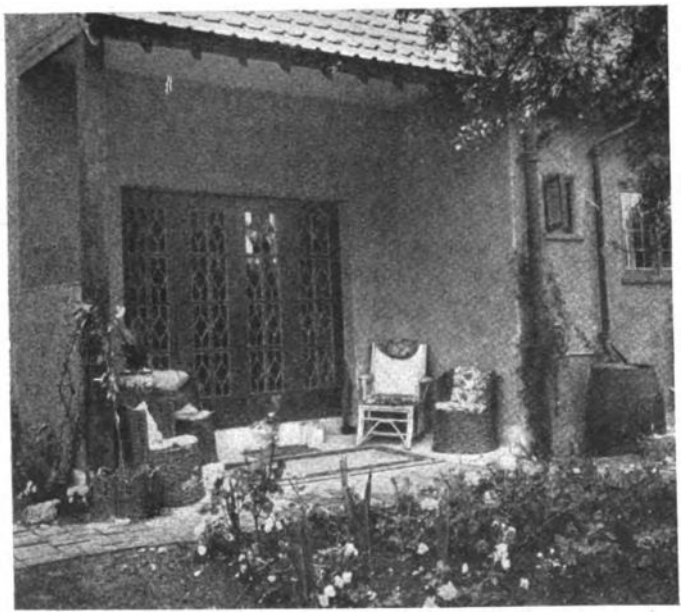
THE JOY OF MAKING A NEW GARDEN

IF one is fond of hard work, to what better use can time be put than in making a garden to one's own plan? Perhaps the following notes and accompanying illustrations may be of interest to others who are about to enter into an entirely fresh place, and I accordingly venture to chronicle the details forthwith.

In December last my brother and I purchased two adjoining houses in Ewell, Surrey, and the prospect that confronted us is clearly indicated in one of the accompanying illustrations. Rather than have two separate gardens, under the conditions of relationship, we decided to join forces and have one in common.

We were lucky to a large degree in living only a matter of three miles or so from the new place and in having a very well stocked garden of ten years standing from which to start the new garden. Some idea as to the quantity of plants, bricks for the paths, crazy paving, sundial, figures, garden tools, etc., that were transplanted may be gathered from the fact that three small motor lorries were required at different times.

PEAR TREE COTTAGE, EWELL, IN DECEMBER LAST.



THE PORCH LOOKING OVER THE GARDEN.

Being the last two houses to be completed, all the material from the previous building operations was dumped on our ground and remained there for some time. Digging operations had to be commenced round this material, so that a start could be made with the planting. The very first items were the three fruit trees, which entered the ground on Christmas Eve. The ground was fearfully weed-ridden, containing hot beds of nettles, thistles, dock, plantain, to mention but a few. Much of my spare time was taken in this early digging and on alternate Saturdays 8.30 a.m. would see me hard at it and, after having moved in, 5.30 a.m. would see me getting in an hour or so before leaving for Town at 8 o'clock.

With the idea in mind of having a design which would involve the least amount of upkeep afterwards and at the same time providing an air of spaciousness, it was decided to devote the main part to a lawn. This necessitated the whole of it being dug over deeply to get rid of the weeds and to render it level.

In order that I could be free to proceed with the digging of the beds, this work was entrusted to a gardener of the old school, who took a personal interest in the job and did it thoroughly, including the sowing of the seed. This and the cementing of the pond were the only items not carried out by family labour.

In the centre of the lawn is a cemented pond in which water lilies, irises, etc., flourish, together with some score of goldfish. A red water lily has already sent up some twenty fine blooms, despite its removal in bad weather.

The goldfish had to exist for a fortnight in the rain-water butt, until their new abode was ready for them. The earth dug from the pond formed the basis for the rock garden in another corner. In tubs around the margin of the pool can be seen the beautiful agapanthus, both white and blue.

Around the three sides of the back garden are broad herbaceous borders in which are all kinds of flowers in their due seasons.

In order to be able to attend to the beds in wet weather without detriment to the lawn, brick paths have been laid round the entire garden, while in front of the two houses crazy paving fulfils the same useful purpose.

The back garden at one end had the natural advantage of some old fruit trees, which are very effective, but otherwise the place was empty and is of our own designing.

Attention is drawn to the small statues, which form a striking note. We are fortunate in each house having a roomy roofed-in loggia, from each of which a good view of the garden may be enjoyed, even in wet weather.

In view of the fact that much inclement weather was experienced when planting was in progress, our losses in plants have been slight, and we feel rather gratified at the result obtained within the space of six months.

J. M. W.

THE GARDEN AS IT WAS LAST JUNE.

THE FRUIT AND KITCHEN GARDEN

Old Walls and Fruit Trees.

OLD walls in a garden are always interesting, but in the case of fruit trees they sometimes form very secure hiding places for insect pests. On the north side moss will grow in the joints, and if it is allowed to remain undisturbed it destroys the mortar, loosening the bricks and making it difficult for the workman to fix the nails securely where nailing is practised. Where walls are needing repairs it is best to loosen the branches and tie them into small bundles, but not tightly, and allow them to remain quite free from contact with the wall while the necessary repairs are being carried out. First scrape away all loose mortar and moss where it exists, then syringe the wall with a strong insecticide, standing directly in front of the wall while forcibly syringing the liquid into the holes as well as the face of the wall itself. Fill up all holes with cement made as follows: Mix two parts of fine sand with one part of quite fresh cement in a dry state, then add water and make the combined parts nicely workable with a small trowel. Old nails can be cleaned by burning them on an old spade or shovel on a fire.

The tying of the branches of the fruit trees away from the wall will retard the development of the buds, thus enabling the cultivator to guard them against late frosts when they expand into full bloom.

It will be a good opportunity to clean the branches of trees that are found to be infested with scale. When the branches are again nailed to the wall make the main ones secure, first allowing the young shoots to depend loosely and away from the wall as long as possible—until the buds begin to swell freely. In the meantime prepare fibrous loam and rotted manure, if the latter is available, in readiness for placing on the border as a top-dressing when the trees are dealt with. Do not trample all the time on the border soil, but make use of some boards or planks for the purpose, and even then lightly fork up the surface or ease the top crust up with the fork after the trees are duly attended to.—HANTS.

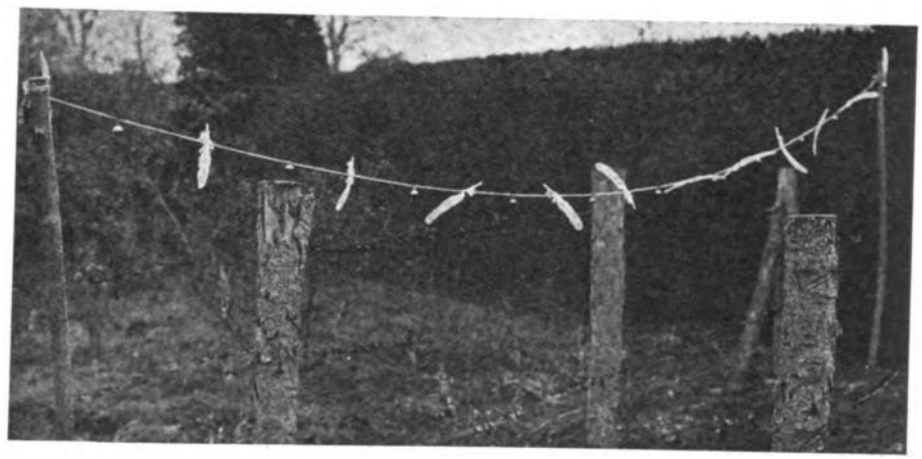
How to Keep Birds from the Fruit Buds.

IF birds prove very troublesome, it may be as well to leave the pruning of fruit bushes until spring unless some sort of protection can be given. The sparrow is the worst destroyer of fruit buds, but he has numerous rivals in destructiveness. There is not only the loss of fruit to be considered, but there is also the damage done to the fruit spurs and, generally, to fruit buds where they are present. The birds peck deep and keen. The tender fruiting wood is left bare and indented by their bills. Permanent injury is done by reason of the removal of the buds and consequent exposure of the inner wood to the severities of the winter.

One plan to protect the bushes is to spray them with some sort of preparation that makes the buds distasteful to the birds. But it is not always attended with success. I have tried fish and herring nets; but I think that threading the bushes with black cotton thread or yarn is more effective. It is true that netting affords a little protection from frost, but the meshing makes havoc among the projecting spurs. In the case of wall trees, wooden studs driven into the wall and the netting hung thereon is the usual method adopted to prevent this. But when winds are very high, the nets come into lashing contact with the fruit spurs and much damage is done. Much less damage results from the use of thread or yarn. Preferably a soft yarn, of light body and dark shade, should be used. Silk or wool from old stockings or a jumper will answer the purpose very well. Hard and close-spun threads are apt to do some damage in several ways, chiefly through cutting into the bark. Dark-coloured yarn is the more effective, because the birds do not observe it until they come in contact with it, and then they fly off in alarm.

The threading should be done before hard weather sets in. The bushes and trees should be pruned and trimmed first. Gooseberries, white and red currants are usually the worst attacked.

Having made up a ball of yarn, begin at the top of the bush or tree, and pass the thread from shoot to shoot, preferably in long, dangling strands. It is a mistake to pull the threads tight. Where the fruit buds are thickest apply a correspondingly greater quantity of threading. Standard bushes ought to have a liberal threading about the base, so as to prevent the birds from entering the heart of the bushes from below.—W.



A USEFUL BIRD SCARE CAN EASILY BE MADE OUT OF STRING TO WHICH ARE ATTACHED WHITE HEN FEATHERS AND SMALL BRASS BELLS.

Raising Early Broad Beans and Peas in Turves.

IN the open border, where the soil is not very clayey, hundreds of amateurs sow seeds of both broad beans and peas directly the weather renders the soil workable. The date generally selected is February 14th. Of course, the ground is cold then and seeds may decay in it; certainly they are slow in germinating. But by sowing at this early date early vegetables are obtained.

Those who possess a cold frame are independent of weather conditions. They should procure some turves, preferably those that were cut and stacked early in October. These turves should be placed grass side downwards close together on the floor of the frame. The grass of turves cut three months ago will have died, but the fibres will be sound and help to bind the soil together. Make holes with a small dibber about 1in. apart in the case of peas and 3ins. in that of broad beans, 1in. and 2ins. deep respectively. Drop one seed in each hole and fill the latter with finely sifted soil, then water through a fine-rosed watering-can. The width of the turves should be 6ins. for peas and 7ins. for beans. The frame lights may be kept closed until the seedlings appear, then admit air freely in fine weather. Only a small quantity of water will be needed while the plants are in the frame. Be sure you do not coddle the plants, as they should be planted out at the end of March or the first week in April. At this latter date they will be about 4ins. high and ready for small sticks, which will break the force of the wind somewhat. In the meantime you should prepare the ground for the plants, digging and manuring it, and if there is a nice warm border available, select such for the plants. The turves are transferred just as they are, plants, roots and all, to the open border. Early varieties, dwarf-growing, are the most suitable, and the outside planting out should be closer than is advisable in the case of open-air raised crops.—G. GARNER.

Best Crops to Grow in a Small Garden.

THE owners of small gardens are, with few exceptions, anxious to grow many kinds of plants in them. I am now referring mainly to vegetables and fruit. Even in the smallest garden—one that is entitled to the name of garden—a tiny border can be devoted to flowers. A few herbaceous clumps and a good selection of about six to nine distinct kinds of annuals will yield during eight months of the year a fairly good supply of flowers for vases as well as keep the spot bright with colour.

In the kitchen garden—the small one—every square yard must be cropped to the best advantage. The present is a very good time to make plans for next year's crops. If certain kinds of vegetables are favoured, they should be given first consideration, and the best positions in the garden should be devoted to them. But there are many persons to whom gardening is quite new, and it is for their benefit mainly that these hints are given.

Dwarf-growing peas should be preferred to tall ones, as the rows of the former can be arranged closer together and really heavy crops of pods gathered from them. Early potatoes—if potatoes are to be grown—should be favoured instead of late ones, as the roots of the former can be grown closer together and, as they are lifted at an early date, a second crop can be grown after them, turnips, late cropped peas—sowing earliest sorts for the purpose—celery, dwarf beans, radishes, lettuce and endive. Of course, a few short rows of early cabbages are useful also, some of cauliflowers, as they are so beneficial to health. Wintertime must also be provided for, and to this end we should grow such

Digitized by Google

vegetables as onions, carrots, beet, leeks, celery, parsnips and a few winter greens. Rhubarb, seakale and asparagus may be included where these are appreciated, and there is sufficient room for them. A few roots of rhubarb will not occupy much space and the returns from them are very good as a rule, so an effort should be made to find the necessary room.

Bush fruits and strawberries, the latter grown more closely together than is usual and treated as biennials—not fruited more than once or, at most, twice—are remunerative. Every year, early July, runners should be rooted on the strawberry-bed for this purpose. Raspberries are indispensable, and at least one hundred canes should be planted now at a distance apart of 9ins. in the rows. Several rows may be grown together for convenience of protection against birds, or one long row by itself. In other cases isolated short rows, according to the space available. Gooseberries are profitable, as the fruit can be used green or when ripe. Bush-shaped apples and pears are the most economical for the small garden, and cordon pears on walls or trained to stakes will yield many fine fruits, and a greater variety can be grown in a small space. Because the garden is small do not be tempted to overcrowd it either with vegetables or fruit trees. Allow each crop decided upon ample space in which to grow.—HANTS.

Collecting Hotbed Materials: Their Treatment.

HEAT, either from hot-water pipes or fermenting materials, placed in a heap is very essential for the welfare of some kinds of plants during the winter and spring months. Anything, therefore, that will engender heat should be taken great care of. I know that many inexperienced persons think that litter, for instance, will be all right if it is simply thrown into a rough heap and left there until it is required for forming hot-beds. It is a mistake to treat litter in this way, because it will heat violently, burn sometimes and then cool suddenly. Afterwards it is very difficult to obtain more heat from such material however carefully it may be treated. All litter, as it becomes available, should be placed in a cool, dry shed where air can pass through freely. It should not be heaped, but spread out loosely; the idea is to prevent heating violently. Some heat will be engendered in any case, but not, if treated in the way suggested, sufficiently to burn. When used in building the hot-bed the litter will afford a good steady heat. If a shed is not available, place the litter on some sticks to keep it clear of the ground and also cover with boards to prevent rain soaking and spoiling it. Old hay, hedge trimmings—those from the sides of ditches and from banks—should be dried, heaped and roughly thatched, also with a view to prevent rainwater entering it and turning it mouldy and useless. With regard to tree leaves, these may be heaped, as they will not heat violently and a little moisture will be beneficial. Water does not enter a heap of leaves readily. If in the early weeks of the new year, litter and leaves are used in almost equal proportions to form hot-beds, the heat engendered will be moderate, generally sufficient, and lasting.—G.

WHAT OUR READERS SAY

GARDEN PATHS.

SIR,—I should be very grateful if you or your contributor, "E. G." (whose notes on path making I found very interesting), could inform me as to the method employed in the making of his cement blocks—as illustrated on page 695 of THE GARDEN for December 4th. I am quite ignorant on the subject of cement casting and desire the most elementary information. Would the blocks be likely to crack if exposed to frost?—K. P. DUNCAN, *Mayfield, Sussex.*

THE TREE OF LIFE.

SIR,—It is quite possible that the plant your correspondents refer to is Bryophyllum calycinum. This member of the Crassula family is very common in some parts of Florida, where it is known as "Live for Ever," though flowering branches of it reach the markets under the name of "Florida Bells." Assuming the plant your correspondents speak of is this extraordinary bryophyllum, they are wrong as to the colour of its flowers, which are pendulous and of a reddish green tint spotted white. I believe it is a native of Mexico.

Looking up the works at hand, the only writer speaking of the "Tree of Life" is J. Murray in his "Dictionary of Plant Names," this term being applied to the Arborvitæ. Bryophyllum calycinum is almost indestructible save by frost. It is commonly said that leaves may be nailed to a picket fence and they will grow. Certainly the leaves, which are fleshy, need but be laid in a moist atmosphere to encourage sprouting of growths all around the edges. The plants grow some 4ft. tall, but are, perhaps, more interesting than ornamental, though the flowering branches certainly are attractive when used in decorations. It is of the simplest culture and can be grown anywhere, even outdoors in these parts, during the summer months. There are several other species of bryophyllum, but the one mentioned is most common.—T. A. W.

LABELS.

SIR,—I note the label question has not yet been solved, and I suppose never will be, for what we want is a label that costs practically nothing and that will last at least for some years. The nearest I can get towards the needful—and I have many hundreds in use—is the machine-sawn lath as used by plasterers for walls and ceilings cut into 12in. lengths. By cutting these 4ft. laths in half and again cutting in half crosswise, I get a half point at one end. The other end is planed on one side, and the pointed ends are then brushed over with creosote to half their length. The planed portion is then painted and written upon before the paint dries. On my soil, creosoting is necessary, for something in the ground literally eats up wood; oftentimes an untreated label, post, and even the bottoms of seed boxes, are rotted off inside a year. I certainly would like that Stephen's outdoor ink, as it would be better than using pencil on wet paint, but such an ink is not obtainable; one cannot even obtain a real garden pencil.—T. A. W., *U.S.A.*

WHITE DELPHINIUMS.

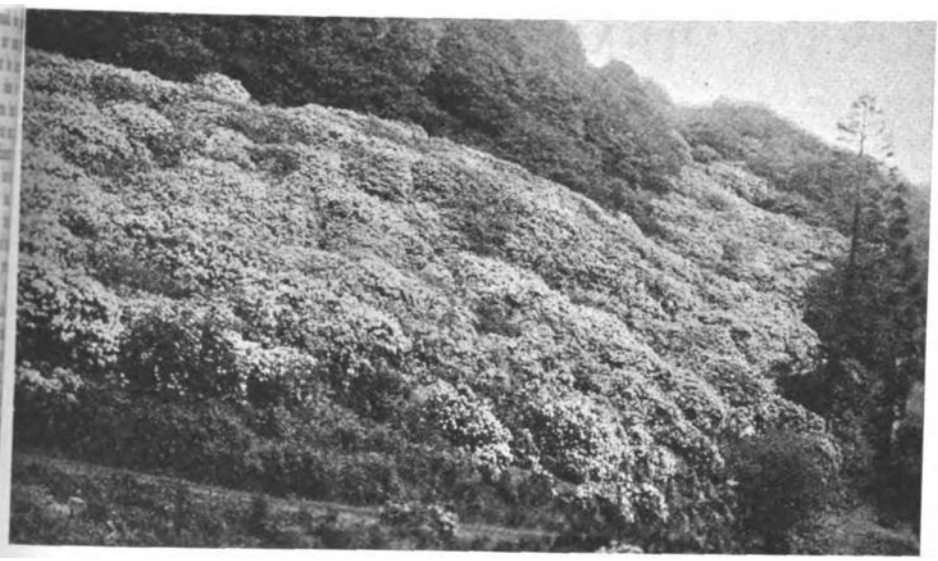
SIR,—It may interest you to know that we have over here several strains of these, the most notable being Toole's, which has been on the market for three or four years. William Toole, an old Britisher, who died last year at the age of eighty odd, was keen on delphiniums, and some years back he was fortunate in finding a white among his seedlings that was much superior to Moerheimi. By selection he succeeded in getting seed that comes all white, though not, of course, all the same type. For a time he offered plants only. His sons, who carry on the business at Baraboo, Wis., still sell plants at 50cts. to $1 each, but seed is also offered, and so far as I have seen, all the plants raised from this seed come white, not cream, but really pure white. Toole's white delphinium seed is offered as Summer Cloud, and embraces selections from the largest and finest whites, some of these bearing individual blooms as large as a dollar piece. Toole's double white, offered as Flora Toole, is available as plants only, no seed being set by this variety.—T. A. WESTON, *New Jersey.*

A FINE BUSH OF KALMIA LATIFOLIA WITH ITS PINK FLOWERS.

KALMIA LATIFOLIA.

SIR,—I have pleasure in enclosing a photograph of a large bush of Kalmia latifolia, covered with lovely clusters of pink, waxlike flowers, growing in the garden of Bryn Mawr, Tan-y-bwlch, which I hope may be of interest to many readers of THE GARDEN. In circumference the bush measures 32ft., and the height is 8ft. 2ins. It is rather overshadowed and sheltered on one side by trees, and above it on the bank is a very large azalea, but it thrives exceedingly on a

Digitized by Google



A BANK OF RHODODENDRONS FORMING A PERFECT SHEET OF BLOSSOMS.

good barrowful of leaf mould twice a year, and occasionally water in a dry season. Undoubtedly this is a plant which deserves to be planted more widely in our gardens.

The second illustration is that of a perfect sheet of rhododendrons which grow on the hillside above the house and kitchen garden and near the woods. It is only a small part of the splendid show of flowers in spring, originally of many good kinds and colours; many have gone back to the ponticum. Still it is a grand show of purple, red, pink, etc. Even the chars-à-bancs stop and the tourists exclaim at their beauty.—L. PERCIVAL (Mrs.), *Merioneth.*

GOOSEBERRY MILDEW.

SIR,—Of the many diseases which injure, cripple and may eventually destroy plants, I am sure that many will agree with me when I say that the ravages caused among gooseberry plantations by American or gooseberry mildew is responsible for more deaths and casualties to these plants than could fall to be accounted for by most other diseases of plant life. Gooseberry mildew can be checked, if not altogether cured, and this important fact I should like to impress upon those who read these notes. By results obtained from experiments of my own, and continued over a few years upon a hundred or two of bushes, I am quite convinced that if spraying be commenced in early spring and be regularly done every week or ten days throughout the summer, affected bushes will present a healthy appearance in a very short time. The work of spraying should be carried out in a thorough and systematic manner, and no parts of the bushes left undone. The results of this regular spraying will be apparent in renewed vigour of the shoots and a healthy green upon the leaves in place of the former sickly white which covered them. The ugly black and charred appearance which the points of the shoots presented will soon be replaced by healthy firm wood. Bushes in some gardens I have observed are allowed to go on in a diseased and unprofitable state year after year, and no really serious attempt ever made to clean or bring them back to health. When they reach the chronic stage, and give one the impression of having been whitewashed, the owner then usually decides to uproot them and have a fire. Burning, without doubt, is most effectual, and puts a final stop to its depredations and a check on its spreading. Keeping old diseased bushes is only nursing a hot-bed of infection, and a menace to any healthy bushes in the vicinity. The mildew can be carried by bees, birds and the wind to gardens and plantations where there may be healthy plants. In my opinion, the spraying of gooseberry bushes should be made compulsory. A combined and systematic effort, however, on the part of all growers, large or small, to put down this mildew scourge and eradicate it from the country would ultimately be attended with successful results. Owing to the ravages of the disease the at one time common and plentiful gooseberry is seriously threatened with extinction.

Regarding insecticides to spray bushes with, there are many on the market. Some are good, others may be dangerous, while others, again, do neither good nor ill. Lime sulphur is very good, but too drastic for some varieties—as White, for instance—if used at full strength, as it will strip off the foliage if so used. Ammonium polysulphide used in conjunction with XL All Mildew Wash I have found to be safest and most effectual if used as per instructions on tins and jars. Both these washes are sent out by Messrs. Richards. I have also noticed very good results from using "Kurmill" on mildew-affected bushes. It is marketed at 2s. 6d. by Mr. S. McGredy of rose fame, Portadown, Ireland.—WM. GRANT.

PROPAGATING DAPHNE GENKWA.

SIR,—Where it is desired to increase the stock of this rather difficult member of the Daphne family, and to have it upon its own roots in preference to grafted plants, many different methods are tried to accomplish this object. Daphne Genkwa does not, however, appear to be at all amenable to the various means suggested in "Gardening Periodicals," and even such as Nicholson's Dictionary, ripened cuttings inserted in autumn being the usual time-honoured formula in both instances. Increasing the stock by means of "layering" and pegging down a branch was also recommended by a writer in THE GARDEN some time ago. The result of this treatment would give "Irishman's cuttings," I presume (cuttings with roots) which could be potted at once. The latter is, no doubt, a sure method but a very slow one. Although Daphne Genkwa is not a deciduous shrub, I find autumn-inserted cuttings do not give satisfactory results; hard wood is slow to callus in autumn and winter, and many would decay before roots were emitted. Instead of inserting the cuttings in autumn, I find that spring-inserted cuttings are more successful, much more satisfactory, surer, and quicker to root.

To secure cuttings in early spring, about the end of December or beginning of January, I introduce a pot or two into a house where there is a temperature ranging from 45° to 55° Fahr.; by the early part of March sufficient cuttings are available to commence with. Cuttings should then be made from the points of shoots, but side growths ought to be made use of also—the latter pulled out with a gentle but sharp nip, which will bring a heel with it. Cuttings should be from 2ins. to 2½ins. long, and a very sharp knife should be used for trimming the leaves and smoothing the joint or heel. The skin of the shoots is very easily torn, which would preclude all chance of cuttings striking, hence the reason for using a sharp knife. The cuttings when ready should then be inserted in a small frame or box containing very finely sifted sharp sand. I usually give the sand a thorough soaking of water first, and let it drain out; another good soaking of water is given when the cuttings are in, through a fine-rosed can. In the case of a frame, the light is put on; if a box, a pane or two of glass. With the exception of wiping the moisture off the glass each morning, the frame is kept close for at least a fortnight. After this gradually admit a little air, until a chink of air can be given day and night. The frame or box should be in a position where a bottom heat of about 55° Fahr. could be maintained.

Under this treatment, in the course of eight to ten weeks, cuttings should be rooted, and should be transferred to thumb pots. The potting compost should consist of about equal parts of leaf-mould (oak for preference) and rough silver sand, a little peat if obtainable, and well mixed. When the plants are potted, they should be placed back in the frame again, given a good watering, and kept rather close for a day or two. When they can keep erect, full ventilation and plenty of air should then be given.—CRATHE.

ROSE AMERICAN PILLAR.

SIR,—The accompanying illustration of rose (American Pillar) may be of interest to many readers of THE GARDEN. The rose was planted in the gardens here (belonging to Mr. John Cuninghame), three years ago and trained to grow over an old, dead apple tree, which had been cut back. It has reached a fair height and is most decorative during the summer months.—THOMAS BARCLAY, *The Gardens, Creich House, Fairlie, Ayrshire.*

A DECORATIVE METHOD OF GROWING ROSE AMERICAN PILLAR.

HINTS WORTH REMEMBERING

Hal, a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Owing to the number of hints which are sent in, we desire that, in future, each hint should be sent in on a post card, and should be limited to 150 words. Payment for these hints is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT.

The Propagation of Anchusa italica.

In some soils this invaluable border plant must be treated as a biennial, for very frequently after the second season of flowering it has exhausted itself, and where the true good types of the Dropmore, Opal and other fine varieties are desired, resort must be had to cuttings, and this is the time of the year to perform this operation. Take up one or two strong specimens of this year's stock with all the roots intact—if any break off while lifting fork them out—now cut off all the small fleshy roots from the main rootstock. The old plant may be replanted at once or laid in the soil until required. The small, fleshy roots that were severed from the old plant should now be cut into 2in. lengths, keeping all of them one way up—square cut at top and slanting at the bottom—tie them in bundles of ten, and lay them in a heap of sand in the open until spring, when, on examination, it will be seen all the crowns will be showing young shoots. Let them grow until green and hard enough to stand transplanting, when they may be put straight into their flowering quarters, where they will make fine sturdy plants for the following season. This method has been practised for years with wonderful success.—F. L. B.

Earthworms in Lawns.

After reading the very useful hints that you have published in THE GARDEN, I feel it my duty to help this good work on, trusting these hints will prove successful. Earthworms in the lawns.—To prevent earthworms doing serious damage to a fine lawn, apply sharp, gritty sand in December and January. This will send them into the lower strata, where they will do no damage and yet assist drainage, aeration and tilling of the soil. To remove them altogether, water after a showery day with a strong solution of "Abol" with fresh lime water. Or, with the more efficacious but deadly poisonous corrosive sublimate (1 oz. in 30 gallons of water applied from a watering can), the worms, being then near the surface, will come out of the ground immediately. Sweep them off in an hour or so and keep the dead worms back from fowls, especially if the corrosive sublimate has been used.—S. E. L.

Propagating Shrubs Indoors.

For those with little space to spare in the garden for cuttings of evergreen and deciduous shrubs the following is an excellent method of increasing stock. In the autumn or early winter months take as many cuttings as are required of strong upright growths of the current year, pull off all the lower leaves and place the cuttings in glass jars filled with water (jam jars will do admirably) in a dim light indoors and leave there till spring, renewing the water from time to time to keep fresh. In February place in a window. By April the stalks should show a number of white roots from 2ins. to 3ins. long. Plant out in desired positions during April, when the rooted cuttings will soon make fresh foliage and within a year or so form well shaped shrubs. I have increased aucuba, laurel, myrtle, euonymus, deutzia, weigela, pyrus (japonica), snow berry, viburnum and many other shrubs by this method. M. H.

Eradicating American Blight.

One of the worst pests of the apple tree is American blight. I have read of many devices to clear the trees, but I have never come across the one I have often used in Tasmania with great success and which is procurable in the smallest village, *viz.*, petrol—it is sudden death. Get an ordinary paint can, put in a small amount of petrol, and with a clean paint brush lightly touch each colony. Mark the place where you start and work round the tree limb by limb, as petrol evaporates so quickly that you cannot see where you have been. It can also be used in autumn-time if care is taken not to touch the leaves or young shoots. (I should have no fear to try it on dormant vines for mealy bug. Will someone try it and let us know the result?)—R. C.

A Remedy for Slugs.

One of the best remedies for the slug pest is made by mixing one part of finely powdered alum with seven parts of slaked lime. This should be very thoroughly mixed together and passed through a very fine sieve. This may be scattered freely on mild evenings when the slugs are above ground. With the exception of the lime-haters, no plants are injured by being covered with the powder.—H. C. W.

Renovating Turf Edges.

To renovate edges of turf that have become frayed and broken, mark off with a spade or turf edger a strip of the turf about a foot wide containing the broken edge in one piece or several, as may be convenient. Detach it from the ground by slipping the spade under it. Move it forward until it projects a couple of inches or so beyond the line of the desired edge, press well into position and make your new edge. Gather the pieces cut off and place them in the space left vacant when moving forward the turf, then fill up this space with soil well pressed (or rolled) down to the required level. You have your new clean edge at once, and in a very short time the grass will have grown over the little patch.—M. A. S.

A Most Artistic and Cheap Method of Staking Flowers.

There is no doubt that in staking a tall-growing perennial, say, a delphinium plant, the most satisfactory way is to use a strong but slender stake for every flower-spike. To get the best stakes for this purpose without cost take in the autumn the strongest stalks of your hardy perennials, such as asters, rudbeckias, golden rods and heleniums, and strip the leaves off, using any thick rag in running the stalks quickly through the hand in order not to hurt it. Thereafter dry the stalks off and keep them in a dry place during the winter. They are ideal in their slender sturdiness, giving the flower spikes sufficient protection against storms and allowing them to sway with the wind instead of being snapped off, as too often occurs when less flexible stakes or canes are used. Lastly, they have the advantage that they are scarcely to be seen as are other staking materials, even with contrasting backgrounds. Thus the plants do not appear to be staked, but seem to grow quite naturally.—M. L. W.

THIS MONTH IN THE GREENHOUSE

Damping in the Late Chrysanthemums.

MANY of the late chrysanthemums stand well until Christmas, when they are naturally very much appreciated. The chief trouble to guard against is damping, which is due to the attacks of a minute fungus. Here many of the petals of the flower fall downwards and finally come away altogether, so that the bloom is a mere apology for what it ought to be. The fungus which causes the disease succeeds where there is a moist surface, so that excess of moisture and a muggy atmosphere favour its propagation. To prevent the trouble take care to give a free ventilation in mild, dry weather. During fog keep the damp air out as much as possible as nothing does so much harm to chrysanthemum blooms as a foggy atmosphere. Water should be given sparingly and always in the morning, so that the plants can dry a little before nightfall. If any heat is available a little gentle warmth will do much to preserve the well-being of the flowers, especially during spells of wet, sunless weather. Examine the individual flowers often and any petals that show signs of being affected should be at once pulled out.—L. B.

Retarding Flowering Plants.

MOST gardeners try to get as many flowers as possible for Christmas, but it may happen that specimens needed for some later festivity, like chrysanthemums and the early bulbs, will reach such an advanced state that they are likely to be over before being required. In such cases it is useful to know that it is quite a simple matter to retard the plants. The specimens should be removed to a cool and, preferably, rather a dark position, such as in the corner of a shed or on the floor of a cellar. Whatever place is selected, one must make sure that the plants are secure against frost. Practically any plants may be kept for a week or ten days in such positions without the least harm. Every day or so they should be examined to see that there is no sign of mildew, which, in the case of chrysanthemums, might do a great deal of damage in a very short while. Any withered foliage should instantly be removed, as it is here that the mildew trouble is most likely to start.—S. LEONARD BASTIN.

Washing Down Greenhouses.

CLEANLINESS of the structures in which plants are grown is absolutely essential if first-class results are desired. With this maxim in mind it is well to proceed with the cleansing of all houses as soon as this operation becomes practicable. House washing, although a simple task, should be done thoroughly and methodically if the best results are to be derived from it.

First clear the house of all pot plants and if creepers are trained up the roof,

Digitized by Google

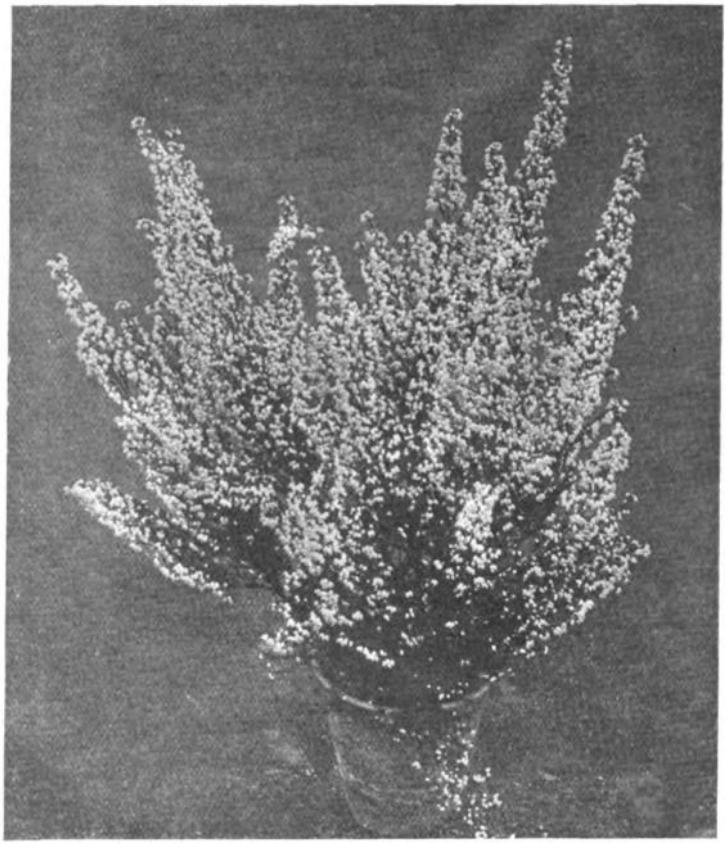
release the ties, cut out any dead or surplus growth and tie the branches loosely together, leaving the creeper suspended by ties of string at a distance of about 18ins. from the glass. Where the house can be entirely cleared of plants it is an excellent plan to burn some sulphur in it the night previous to washing down. If possible select a dull or rainy day for the work, as dirty water is not them so liable to dry on the glass and woodwork as it is on sunny or windy days.

On the morning of the selected day syringe the whole house down with soft soap dissolved in water, to which paraffin has been added at the rate of a small thumb pot to the bucketful. If left for about an hour this has a wonderful effect in softening and loosening the dirt.

Scrub the woodwork and glass with the same mixture of soft soap and paraffin, working in sections and proceeding from the top downwards. The overlaps of the glass may be cleaned out with the aid of a thin piece of zinc. As each section is completed, give it a good syringing down with clean water. When the whole house is finished admit plenty of air so that the superabundance of moisture may be dried up. To complete the work all brickwork should be lime-washed, taking care to get the wash well into all the crevices so that any lurking insects or eggs may be destroyed. The creepers may then be tied into place after they have been inspected to see that they are free from pests and finally the pot plants brought back, taking care that they too are quite clean.—T. H. EVERETT.

Dwarf Heaths in Pots.

DWARF heaths are again becoming common and, since they are delightful little things and popular, we give a few notes on how they may be kept and grown on. The varieties commonly found are species of erica, often E. hyemalis, E. gracilis, E. persoluta and E. caffra; the name matters little, if the blossom proves suitable for decoration. With a little care the plants can be kept fresh and healthy for quite a long time; they must, however, be kept out of a draught, away from coal and gas fires and carefully watered before the soil gets just dust dry—a difficult problem really and the one which leads to great mortality among them; dipping the pot in a basin of tepid water is the best plan, and always see that it drains for ten minutes at least before it is replaced in any saucer or ornamental bowl. When the flowers fade they may be pinched off; a little later repot the plants into pots a size larger, using a compost of loam (turfy), peat and leaf-soil. With a little bottom heat they will soon come away nicely and by another year prove equally fine and a trifle larger—they grow slowly. Feed when growth becomes speedy and give plenty of ventilation in summer.—CLYDESDALE.



MANY OF THE DWARF HEATHS MAKE EXCELLENT INDOOR DECORATION.
This is a white-flowered variety of Erica gracilis.

Stoking.

A SAVING of fire heat can be made by congregating the plants into as few structures as possible, even if they do suffer a little in consequence. But, needless to say, the greatest economies of all will be effected in the stokehole. Stoking is admittedly one of the most disagreeable, albeit one of the most important, operations in horticulture. Except at "banking up" time it is not a good policy to have a crammed fire, as this blocks the passage of air without which the proper combustion of the coal cannot take place. A small red or clear fire in which the fuel is fully combusted results in greater heat with economy in coal and time required in stoking.

Such a fire is more agreeable and easier to manage and is always under the control of the stoker, a point which is most important if following a night of frost comes a day of bright sunshine, when fire heat would be a needless waste and give rise to conditions in which pests of various kinds seem to flourish. In such circumstances all draught should be shut off and the front of the fire well packed with damp ashes.

It is obvious that efficient stoking requires an intelligent consideration of the weather conditions. Having stored up all available solar heat by timely closing down of the ventilators, the idea of having fire heat to supplant its exhaustion is a good line to follow in the maintainance of an even temperature.

Preparatory to restarting the fire, draw out the damper full length to carry off any sulphurous fumes. In stirring the fire see that the tool used passes along the bars to the back of the furnace. Then use it as a lever to stir up the fuel, removing all clinkers and dirt and cleaning out the ash box.

Feed the fire with a small quantity of dry fuel again replenishing it as the fire burns clearly, setting the damper to give the required draught. In banking up the fire for the night see that the various temperatures are as required, a little above will not be a great fault. Stir up the fire, shut the furnace door with full draught on to get a clear, bright fire, fill up the furnace with finely broken fuel to admit of a good quantity. Use the damper only as a means of controlling the draught, leaving 1in. to 2ins. open as practice and weather considerations dictate.

The use of ashes at the "banking up" time is open to contention as this means more clinkers in the morning. But if the lasting properties of the fire are at all doubtful a little may be thrown on to steady it.—WM. MCCARRELL.

Renovating Vine Borders.

WHERE vine borders are in an exhausted condition no time should be lost in making the border good, presuming the fruit has been harvested. Before removing any of the old border the new soil should be got in readiness. The soil for this purpose should consist of good fibrous loam that has been cut and stacked for six months in a fairly dry shed. It is then in a fit state for use, chopping it into pieces 3ins. or 4ins. square, so that the compost is on the lumpy side. To every cartload of loam add one barrow-load of broken mortar and the same amount of wood ashes and charcoal combined, 8lb. or 9lb. of ½in. bones, and half that quantity of horn or hoof manure, if procurable, or any other manure that is lasting and good, and two or three shovelfuls of fresh slaked lime. This compost may be turned over to get it well mixed. Repeat the above mixture until sufficient soil is got in readiness for the work to be done. The loam is much the best if it can be procured from old pasture land where cattle have been feeding for many years.

When clearing away the old exhausted soil from the border, I would advise clearing half of the border first, cutting it through with a spade down to the drainage, severing the roots with the spade as the work proceeds. After the soil is all cleared, remove the drainage and pipes to get a clear bottom to work upon. When removing the other half of the border, this may be done with a fork. Great care must be taken not to damage the small fibrous roots as the work proceeds. As the roots are exposed they should be secured and tied up with soft string out of the way of the fork while the unearthing is done, keeping them moist when exposed by syringing them occasionally. If there is about 9ins. or a foot of the old border left untouched close to the stem of the rods, it is a great help to the vines, as they are not so liable to flag. All drainage and pipes should be cleaned and put back into their proper position. If the drainage is insufficient, more may be added to make up a total depth of 9–12ins., on top of which put a thick layer of newly cut loam, placed grass downwards, and then proceed by wheeling in the newly prepared soil, spreading it evenly over the surface about 4ins. or 5ins. thick, and give each layer of soil a good ramming, making the border very firm. Vines dislike spongy soils in which to grow. As the work proceeds the roots may be laid out in position and given enough water to keep them moist. Take care not to damage the roots when ramming the soil. When the work is completed the vines may be syringed once or twice a day if the sun is very bright and the vinery kept rather close for a week or two until root action takes place.—A. GROWER

OUR SERVICE BUREAU

Though so many subjects are dealt with in each issue of THE GARDEN, *it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, there is always information available from a staff of expert contributors and consultants; and there is no charge for this. It is one of the additional means of service which* THE GARDEN *is glad to render to its readers.*

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope and the coupon that will always be found in each issue, shall be sent with the enquiry. We would point out, however, that we cannot undertake to supply readers with plans and designs of gardens, but will willingly assist in giving suggestions for planting.

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2.*

We have selected the following enquiries, with their answers, as being of more general interest, and therefore worthy of publication.

The Propagation of Primula rufa.

Can you kindly tell me whether Primula rufa seed will germinate in a cold frame if I keep the frost out? I believe that P. rufa, like P. Forrestii, is not a hardy outdoor primula, but whether it needs artificial heat to germinate, I know not. I have sown it in a cold frame hoping that it may germinate in the spring with spring warmth.—V. C., Chander's Ford.

Seed of Primula rufa should germinate in a cold frame, such as you have. The seed should be sown in pots and plunged in the frame. Do not be disappointed, however, if germination does not take place early next year. In many cases seeds of these primulas take about two years to germinate. As you say, P. rufa is very similar to P. Forrestii. They like similar positions in the garden, namely, a vertical crevice in the rockery or rock wall. We do not think it is so much a question of hardiness with this plant as one of situation. P. Forrestii is quite hardy in several gardens in the south and west, and also towards the north, so that we think you will find there will be no difficulty in growing it, although it is a somewhat peculiar plant.

Apple Canker.

I enclose cuttings of apple tree Stirling Castle to ask what has gone wrong. The tree is about fifteen years old, on south facing wall in kitchen garden. Last year it had a good crop and a trace of canker showed. This year no crop and the canker seems to be spreading all over it. Can anything be done or must it be taken out and burnt? Also, is there danger of it spreading to the other trees?—M. C. B., Annan.

The disease on the shoots of the Stirling Castle apple that you sent for our inspection is the ordinary apple canker. This, of course, will spread fairly rapidly and perhaps infest neighbouring trees. The only remedy is to cut out every scrap of diseased wood and to burn it; though if the greater part of the tree is infected, then it would be simplest and advisable to grub it up entirely. Spraying is of little or no value as a means of checking this disease. It is a curious thing, but badly cankered apple trees invariably crop heavily for the season or two preceding their failure and gradual death from this disease, the cankered patches having much the same effect upon the fruiting branches as the branch ringing operation.

A Pear Tree with Damaged Bark.

I should be very grateful if you would advise me what to do for a young pear tree (about fifteen years old), which has been badly barked all round—about the depth of a foot—I think it must have been done by pigs. I did not discover it until lately, but the tree appeared to be ailing. The foliage looked as if it had been caught by the late severe frost we had and it did not bear this year. Would grafting wax on the edges of the wound be of any use? Or must the tree inevitably die? It is usually a most prolific tree. It is a Williams' Bon Chrétien.—M. H., Newport, Salop.

The Williams' Bon Chrétien pear tree that has been badly damaged by animals gnawing the bark, is certainly in a very precarious state, if the bark has been taken off all round, so that the stem is completely girdled. The smallest channel of bark left connecting top and bottom of the wound would be sufficient to save the tree, but failing this—if there is no connecting strip between top and bottom edges of the wound—the tree will die unless it is bridge-grafted early next spring—in early April. By this operation scions are grafted on to the stem so that they join at the top and bottom edges of the wounded bark, and so bridge the gap. It is an operation that calls for some skill and an experienced knifesman should be employed for the work, should you consider the tree worth the trouble and expense. No amount of wax, paint or tar coverings can remedy the damage, we fear.

Musty Apples.

I have been eating Warner's King apples up to now, and although they look perfectly sound, I find that when baked they are very earthy or musty to the taste, and last night an apple Charlot made of Newton Wonder apples was on my dining table, and I find them even worse than the Warner's King, so bad in fact as to be uneatable. I had a new fruit house built in accordance with the instructions you were good enough to send me recently, therefore I do not think it is anything to do with the way they are kept; I am wondering, therefore, if you would be kind enough to give me any information that would help me to avoid this trouble another year.—J. W. B., Old Catton.

We think that the tainted flavour of the apples must be due to their having been stored on scented or unseasoned wood, in straw or hay, or upon some material or other from which this musty or earthy flavour could be acquired. If these apples were stored close to potatoes or any vegetable, they would quickly absorb their characteristic scent, of course, and so become tainted. There is little likelihood of the fruit having been so tainted on the tree, and we think if you closely examine the store conditions you will find the fruit has been upon, or adjacent to strong smelling materials of some kind or other.

Spraying of Fruit Trees.

I have about one-fifth of an acre orchard under young bush apples and pears of varieties planted as two and three year old bushes in 1924. This summer Irish Peach had apple mildew, and leaf scorch was fairly prevalent. I have since applied potash (as sulphate of potash). I sprayed once during the summer with lime sulphur at 1 in 75. My plums and damsons suffered in varying degree from aphis (green variety). Black aphis was also found on some apples. As I have obviously both fungi and insect pests to deal with, I propose to spray twice during the dormant season, once with lime sulphur and once with Mortegg. My plan was to spray shortly with the lime sulphur (1 to 20), following with 7½ per cent. Mortegg, say, in January. Is this sound, or would you reverse things and use the Mortegg first? One other point, would you vary the strength of either or both these washes to suit different varieties? For instance, is lime sulphur, 1 in 20, too strong as a winter wash for Cox's Orange and perhaps James Grieve and Newton Wonder?—A. A. M., Bridport.

Regarding the winter spraying of your fruit trees, we would first point out that it is quite unnecessary to use both the winter washes you mention, and we think your best plan would be to spray the trees with Mortegg wash in late December or early January at the strength you mention. The lime-sulphur wash applied at this season will have little fungicidal value, and will certainly not help to control the apple mildew with which some of your trees are infected. The remedial measures to adopt for the mildew are as follows:

1. Cut off all infected shoots at once. These can be recognised by the "white" appearance of the wood or the brownish shrivelled shoot tips.

2. When the buds expand in spring go over the trees and cut off all infected parts, whether these be flower trusses or small leaf clusters.

3. If, after removing all these primary infections, your trees are liable to serious infection from neighbouring gardens, then spray with lime-sulphur shortly after the blossoms set. For this spraying use the lime-sulphur at 1 in 30 for all except the very tender sorts, like Cox's Orange, James Grieve and Newton Wonder, on which 1 in 60 should be the strength of wash applied.

To keep down the aphis attacks, the Mortegg will prove effective and will, at the same time, considerably reduce the numbers of all other pests. A 7½ per cent. Mortegg wash appears safe to use on all varieties, but the maker's directions should in every case be closely followed.

Treatment of Young Japanese Cherries.

I have some young Japanese cherries, which have been planted about three years. They have this year thrown out shoots 18ins. to 24ins. long or more, which have no sign of flower buds, only leaves. They have all along been inclined to run to leaf rather than flower, but I do not want to shorten back the shoots, as I want them to grow high, not remain in bush form. Would you advise root pruning, either all round or half round, or replanting? The soil is a rich, heavy clay, only lately taken in from a field.—M. H., Pinhoe.

The luxuriant growth is very welcome and quite normal for newly planted trees in good ground. When once the plants begin to flower it is often a difficulty to obtain vigorous young growths. We advise you to do no pruning other than thinning crowded branches, or shortening any which are very long and likely to destroy the balance of the trees.

A Hedge of Sweet Briar.

I am about to make a sweet briar hedge (Penzance Briars). What would be about the proper distance apart to plant the briars?—J. H. S., Leicester.

We should suggest that you plant Penzance briars for the purpose of making a hedge about 2ft. 6ins. to 3ft. apart. This will, in time, form a dense-growing and neat hedge.

CLEAN CROPS *ARE* GOOD CROPS

New plant hygiene

THE slug is a great destroyer — and, hidden in the soil by day, he carries on his depredations largely immune from attack *till you discover* HELICIDE.

HELICIDE is the liquid soil cleanser which can be used without harm to growing plants. Not only does it destroy slugs. It is the prime agent in securing clean, healthy turf, free from worm casts.

Worms in the lawn!

HELICIDE is the ideal wormkiller. Far cheaper than powders, it is easier to apply, and more effective too. Write now for full particulars. 1 pint makes 40 Gallons of Liquid.

USE HELICIDE

Pint tins - 1/9
Quart tins - 3/-
Gallon cans - 7/6

SERVICE BUREAU.—*Continued.*

Shrubs from a Seaside Garden.

I move into a new bungalow in March next. It is situated overlooking the sea on the south coast of Cornwall, facing due south. The front is bare and ugly and I wish to cover it from the ground to the top of the windows—about 12ft. with some "quick growing" flowering shrub or creeper. The walls are concrete with smooth surface.—G. H. G., Devon.

There are a number of subjects which would be suitable for your purpose, and we give the names of one or two, from which you might select one which you consider suitable. Berberidopsis corallina is a handsome Chilian evergreen shrub, which carries drooping clusters of scarlet or crimson flowers in summer. It is an excellent plant for training on a south wall in south Cornwall, and prefers fairly rich, sandy loam. Solanum jasminoides is a deciduous South American climber. Its bluey-white, star-shaped flowers are carried from August to October. This plant grows well against a south wall in deep, light soil. Tecoma radicans is a vigorous growing climber, with yellow and red flowers, well suited for covering south walls. Magnolia grandiflora is a very fine evergreen; one of the loniceras, several of which are suitable, or wistaria would also do.

Vine Pruning.

I should be very grateful if you would tell me how to treat a vine after fruiting. Should the stem be scrubbed and painted and if so, with what? I have a Muscat of Alexandria which has been badly attacked by blight. I think it is white fly. We have had this very badly and many plants have been damaged. No amount of fumigating appears to kill them. Can you tell me what to use to get rid of this pest? I should also be most grateful for the address of the violet growers, the Misses Allen, I have been unable to find it.—B. M. H., King's Langley.

When a vine has fruited, all young lateral shoots, and sub-laterals, formed on the fruit-bearing branch, should be cut off, and just the tips of the fruit-bearing branches, too. In due course, about the third week in December, have the vines pruned back to two "eyes"—buds. In the meantime, ventilate the house freely. Do not peel the rods, but simply rub off any loose bark with the hand. The rods, but not the "eyes," may be washed. Probably the white fly has been introduced through pot plants. Darlington's original Auto-shreds will destroy it and not harm any plants in the structure. We think the violet grower to whom you refer is: Miss K. Allen-Brown, Violet Nurseries, Henfield, Sussex, who specialises in violet culture.

Pruning of Plum Trees.

Could you advise me about the pruning of plum trees about ten years old, which are planted in a hen run and have not been pruned at all, but have made great growth, about 16ft. high, and thick all through? They do not bear any fruit.—M. N. H., Exbury.

No doubt the plum trees growing in the poultry run are making rather too much growth for them to settle down to fruiting just yet. In such a position they would be in somewhat rich land, conducive to rank growth. This being the case, we would suggest root pruning them this winter. Just take out a trench round each as far out as the branches extend, and cut back the coarse lateral and downward striking roots that are encountered. This will check growth and encourage fruitfulness. The pruning of the branches, best done as early as possible, should be light and, under the circumstances, we would suggest that you do no more than thin out the crowded young growths, cutting them back to two bottom buds and cutting away crowded and crossing branches so that each has plenty of room. It is always best to try to keep the centre of the tree fairly open and free from growth. The well placed young growths should be left intact, but the very long ones might be shortened by about one third. Drastic "thinning out" is the most important item.

Silver Birch.

Can you tell me if I can get young silver birch trees with silver bark to them? I have been told that I cannot, as the bark does not change its colour to silver until the plants are from ten to fifteen years old.—H. H., Cardiff.

No birches get the final colour of their bark until they are some height. Your informant, however, was wrong in his calculations, because the bark does not take its final tone until the plant is 10ft. or 15ft. high—not ten or fifteen years old—a very different matter! This means that if you get three year old plants they should begin to form the silver bark with you in about four years time.

A REQUEST TO ALL OLD READERS

SOME of the older readers of THE GARDEN have pointed out that there are numbers of the fraternity of amateur gardeners throughout the British Isles, who have not read this paper. THE GARDEN is calculated to render them the best attention by giving seasonable advice on planting and sowing and by solving the problems and difficulties that at times beset all gardeners. Some of our contributors suggested a few weeks ago that an acceptable present to send a friend would be a copy of the paper for a year. It was a capital idea and one that we hope will bear fruit, but many of our older readers think that it went scarcely far enough, so they have suggested to us that a further appeal might be put forward. THIS IS THE APPEAL: That *every* reader should pass on the copy of the paper to someone whom they know does not take it in, but who would like to read it. Everybody has some friend whose hobby is gardening, yet seldom reads a paper about it! Readers of THE GARDEN will agree that such friends are the poorer for not making the acquaintance of our paper.

JOIN THE CIRCULATION CIRCLE AND PASS IT ON

If you become a regular reader of the paper, it will increase your interest in your garden because it is specially intended to help amateurs. Amateurs comprise the greatest number of gardeners. THE GARDEN is published every Thursday. It says what it has to say in plain language, free from ambiguity, so that the beginner cannot fail to understand. It is noted for the wealth of its good illustrations. As you will see, they speak for themselves.

You may have failed last year with certain crops. It may not have been entirely "the fault of the season." Or some plants did not turn out quite to your satisfaction. Perhaps you have fruit trees that are not yielding what you think they should.

Remember THE GARDEN caters for all departments of horticulture. It is out to give the best advice, the best news, and the best service to a wider circle of readers. That is its policy. It will be pleased to be of service to YOU.

If you experience any difficulty connected with your garden—however small that garden may be—write to the Service Bureau giving the facts briefly, and they will suggest what should be done.

YOU CAN GIVE NO BETTER GIFT

to your friend, either at home, in the Colonies, or abroad, than a weekly copy of

THE GARDEN

It means 52 remembrances of friendship in the year

If you will fill in the form below, we do the rest.

HORTICULTURAL CROSSWORD SOLUTION.

THE following is the solution of the Crossword Puzzle printed in our Correspondence columns last week:

ACROSS.

1 Berberidopsis, 12 Rue, 13 Charmer, 16 La, 17 Lasthenia, 18 Rail, 19 Lote, 21 Eupepsia, 23 Anil, 24 Maslin, 25 Dc, 26 Recherche, 30 Mate, 33 Datura, 36 Kalm, 38 Nut, 39 Waling, 41 Ryot, 42 Tu, 43 Inulahelenium.

DOWN.

1 Bellardii, 2 Era, 3 Rustic, 4 Betel, 5 Echeveria, 6 Rheum, 7 Ian, 8 Dries, 9 Persimmon, 10 Iliad, 11 Salicetum, 14 Maple, 15 Rain, 20 One, 22 Pack, 27 Hull, 28 Ran, 29 Harl, 31 Anti, 32 Tutu, 34 Awn, 35 Tau, 37 Lye, 40 Ge.

NEW CHRYSANTHEMUMS.

AT their last meeting for the year, on December, 13th, the Floral Committee of the National Chrysanthemum Society had five novelties before them and awarded their first-class certificate to the following:

CRIMSON CONQUEST.—A neat Japanese variety of considerable freedom, but the flowers display a tendency to show a centre. The colour is a reddish bronze. Shown by Mr. H. Woolman.

FUSILIER.—A large single of good form. The regular florets are of rich ruby crimson colour brightened by a narrow yellow zone. Shown by Mr. H. Shoesmith, jun.

LAVINIA.—Another good large single and of bronzy apricot colour lightly flushed with rose. Shown by Mr. H. Shoesmith, jun.

YELLOW FAVOURITE.—A useful sport from the well known variety. The colour is a clear sulphur yellow. Shown by Mr. A. G. Virten.

CATALOGUES RECEIVED.

Messrs. Carter and Co., Raynes Park, London, S.W.20.—The arrival of the seed season is heralded by catalogues from all the leading seedsmen of the country. The seed manual of this firm has been revised and enlarged, and its contents should prove of great interest to gardeners of all kinds. A wide selection is offered in vegetable as well as flower seed, among which are numerous novelties and long lists of first-class varieties. Such novelties as Carter's Rose Queen aubrietia, Carter's Azure Blue forget-me-not, a new compact-growing strain of eschscholtzias, as well as a number of beautiful hardy primulas are noted. Every keen gardener should possess this profusely illustrated catalogue.

Messrs. Dobbie and Co., Limited, The Royal Scottish Seed Establishment, Edinburgh.—Although sweet peas and Scotch seed potatoes have made the name of Dobbie long famous throughout the horticultural world, this firm sends out also flower and vegetable seed of equally high quality. Their excellent catalogue contains careful descriptions of the various up-to-date varieties as well as a wealth of useful information on culture.

Messrs. Dickson and Robinson, Cathedral Street, Manchester.—New culinary peas, new runner beans, a fine strain of onions, a remarkable strain of new hybrid lupins and a race of giant stocks are a few of the items of interest in this firm's seed catalogue.

Messrs. W. Power and Co., Waterford.—This firm's handy and useful tree and shrub catalogue has just come to hand. Trees and shrubs for every type of soil and aspect are included, as well as notes on planting, pruning and cultivation. Several pages are devoted to selected lists of roses for bedding and pergolas, while those who are contemplating tree or shrub planting on a large scale will be interested in the section dealing with forest trees and hedging plants.

Messrs. R. Wallace and Co., Limited, The Old Gardens, Tunbridge Wells. Hardy plants for alpine gardens, bog gardens and herbaceous borders.

Messrs. Elisha J. Hicks, Hurst, Berkshire. An illustrated rose catalogue, including a number of gold medal roses.

Messrs. Laxton Bros., Bedford. A descriptive catalogue of apples, pears and bush fruits. Several new fruits are listed and numerous excellent illustrations are included.

Messrs. Keith Luxford and Co., Chrysanthemum Nurseries, Sawbridgeworth, Herts. Perpetual carnations and chrysanthemums, including both early-flowering border varieties as well as large flowered Japanese, incurved Japanese and decorative chrysanthemums, for the greenhouse.

Messrs. Lowe and Gibson, Crawley Down, Sussex.—Border carnations and bearded irises. Several most attractive novelties for 1927 are noted.

Messrs. D. and W. Croll, Limited, Dalhousie Nurseries, Dundee.—A catalogue of Grampion-grown seed potatoes and gladioli for spring planting. Claymore and Clovullin, two fine new potato varieties, are listed.

Mr. Charles Wright, Takeley, Essex.—British-grown roses and fruit trees.

Backhouse Nurseries, Limited, York.—Trees, shrubs, roses, climbers, etc. Hardy trees and shrubs, which are suitable for town gardens, seaside gardens, as well as the rock gardens are given.

The Wild Garden Nurseries, Rockbeare, near Exeter, Devon.—An interesting list of native plants which are suitable for naturalising in the wild garden, woodland, by the waterside, in the crevices of old walls, etc. These native species are perfectly hardy, they flourish in any odd corner of the garden, and continue to bloom year after year without attention. Good selections of native ferns and orchids for the rock garden are included.

Messrs. Barnards, Limited, Norfolk Iron Works, Norwich.—Garden requisites, such as arches, chairs, tables, barrows, tennis-court enclosures, fruit enclosures, fencing, and wire netting.

Messrs. J. Cheal and Sons, Limited, Lowfield Nurseries, Crawley, Sussex.—A classified and descriptive list of roses as well as an extensive catalogue of trees, shrubs, American plants, climbers and hedge plants. Intending purchasers of trees and shrubs, particularly owners of new gardens, should make a point of studying these catalogues. In them will be found the best of the hedge plants and ornamental trees, both common and uncommon.

Messrs. W. Watson and Sons, Limited, Killiney Nurseries, Killiney, County Dublin.—This firm have sent us a rose catalogue which gives numerous very useful cultural hints on rose planting and pruning and the positions in which various classes of roses should be planted. Lists of hedge plants and fruit trees have also been received.

Messrs. Ramsays, Ballsbridge, Dublin.—Roses, fruit trees, conifers, deciduous and evergreen trees and shrubs, and climbers.

Messrs. W. H. Simpson and Son, Birmingham.—Bulbous plants, delphiniums, perennial asters, lupins, phloxes, and this firm's famous strain of antirrhinum seed are included in their catalogue.

TRADE NOTE.

ALL book lovers will be interested to see the catalogue of farming and gardening books sent out by Messrs. W. and G. Foyle, Limited, of Charing Cross Road, W.C.2. The list, although not comprehensive, is sufficiently large to be of considerable interest to all amateur gardeners. Many second-hand volumes of merit are listed, in addition to the majority of new and up-to-date books on the subject. We commend it to all amateur gardeners who are interested in the gardening section of their library.
